## PREFACE

This report describes the Interim Remedial Actions (IRAs) conducted at the Landfill and Waste Accumulation Area, site LF01, and the Spill/Leak #3, site ST07, located at the Cape Lisburne radar installation in northern Alaska. IRA activities at the sites were conducted during September 1994, May 1995, June 1995, and August 1995. The sites were characterized based on sampling and analyses conducted during Remedial Investigation (RI) activities performed during August and September 1993, and IRA activities at the sites. This report was prepared by ICF Technology Incorporated.

This report was prepared during May through November 1995. Mr. Samer Karmi of the Air Force Center for Environmental Excellence was the Alaska Restoration Team Chief for this task.

Approved:

---

Thomas McKinney  
Program Director  
ICF Technology Incorporated

## **NOTICE**

This report has been prepared for the United States Air Force (Air Force) by ICF Technology Incorporated for the purpose of aiding in the implementation of IRAs and RIs and Feasibility Studies under the Air Force Installation Restoration Program (IRP). As the report relates to actual or possible releases of potentially hazardous substances, its release prior to an Air Force final decision on remedial action may be in the public's interest. The limited objectives of this report and the ongoing nature of the IRP, along with the evolving knowledge of site conditions and chemical effects on the environment and health, must be considered when evaluating this report, since subsequent facts may become known which may make this report premature or inaccurate. Acceptance does not mean that the Air Force adopts the conclusions, recommendations or other views expressed herein, which are those of the contractor only and do not necessarily reflect the official position of the Air Force.

Government agencies and their contractors registered with the Defense Technical Information Center (DTIC) should direct requests for copies of this report to: DTIC, Cameron Station, Alexandria, Virginia 22304-6145.

Non-Government agencies may purchase copies of this document from: National Technical Information Service, 5285 Port Royal Road, Springfield, Virginia 22161.

## **1.0 INTRODUCTION**

This report describes the IRAs conducted at the Cape Lisburne radar installation during September 1994, May 1995, June 1995, and August 1995. The activities conducted include the excavation and containment of drums, soil, and liquids from the Buried Drum Area located within the Landfill and Waste Accumulation Area, site LF01, and the construction of a water collection and treatment system at Spill/Leak #3, site ST07.

The IRAs at the sites were conducted in accordance with the Work Plan and Sampling and Analysis Plan (SAP) for IRAs, Cape Lisburne Radar Station, Alaska, dated 25 August 1994 (U.S. Air Force 1994a), the Addendum to the IRA Plan, dated 06 December 1994 (U.S. Air Force 1994b), and the Cape Lisburne IRA Health and Safety Plan (U.S. Air Force 1994c).

Section 1.0 of this report presents the background and objectives of the two IRAs conducted at the Cape Lisburne installation. Section 2.0 describes the IRA at the Landfill and Waste Accumulation Area (LF01). Section 3.0 describes the IRA at Spill/Leak #3 (ST07). The conclusions and recommendations are presented in Section 4.0. Photographs taken during IRA activities are presented in Appendix A. Laboratory reports for all analytical data are presented in Appendix B.

### **1.1 BACKGROUND**

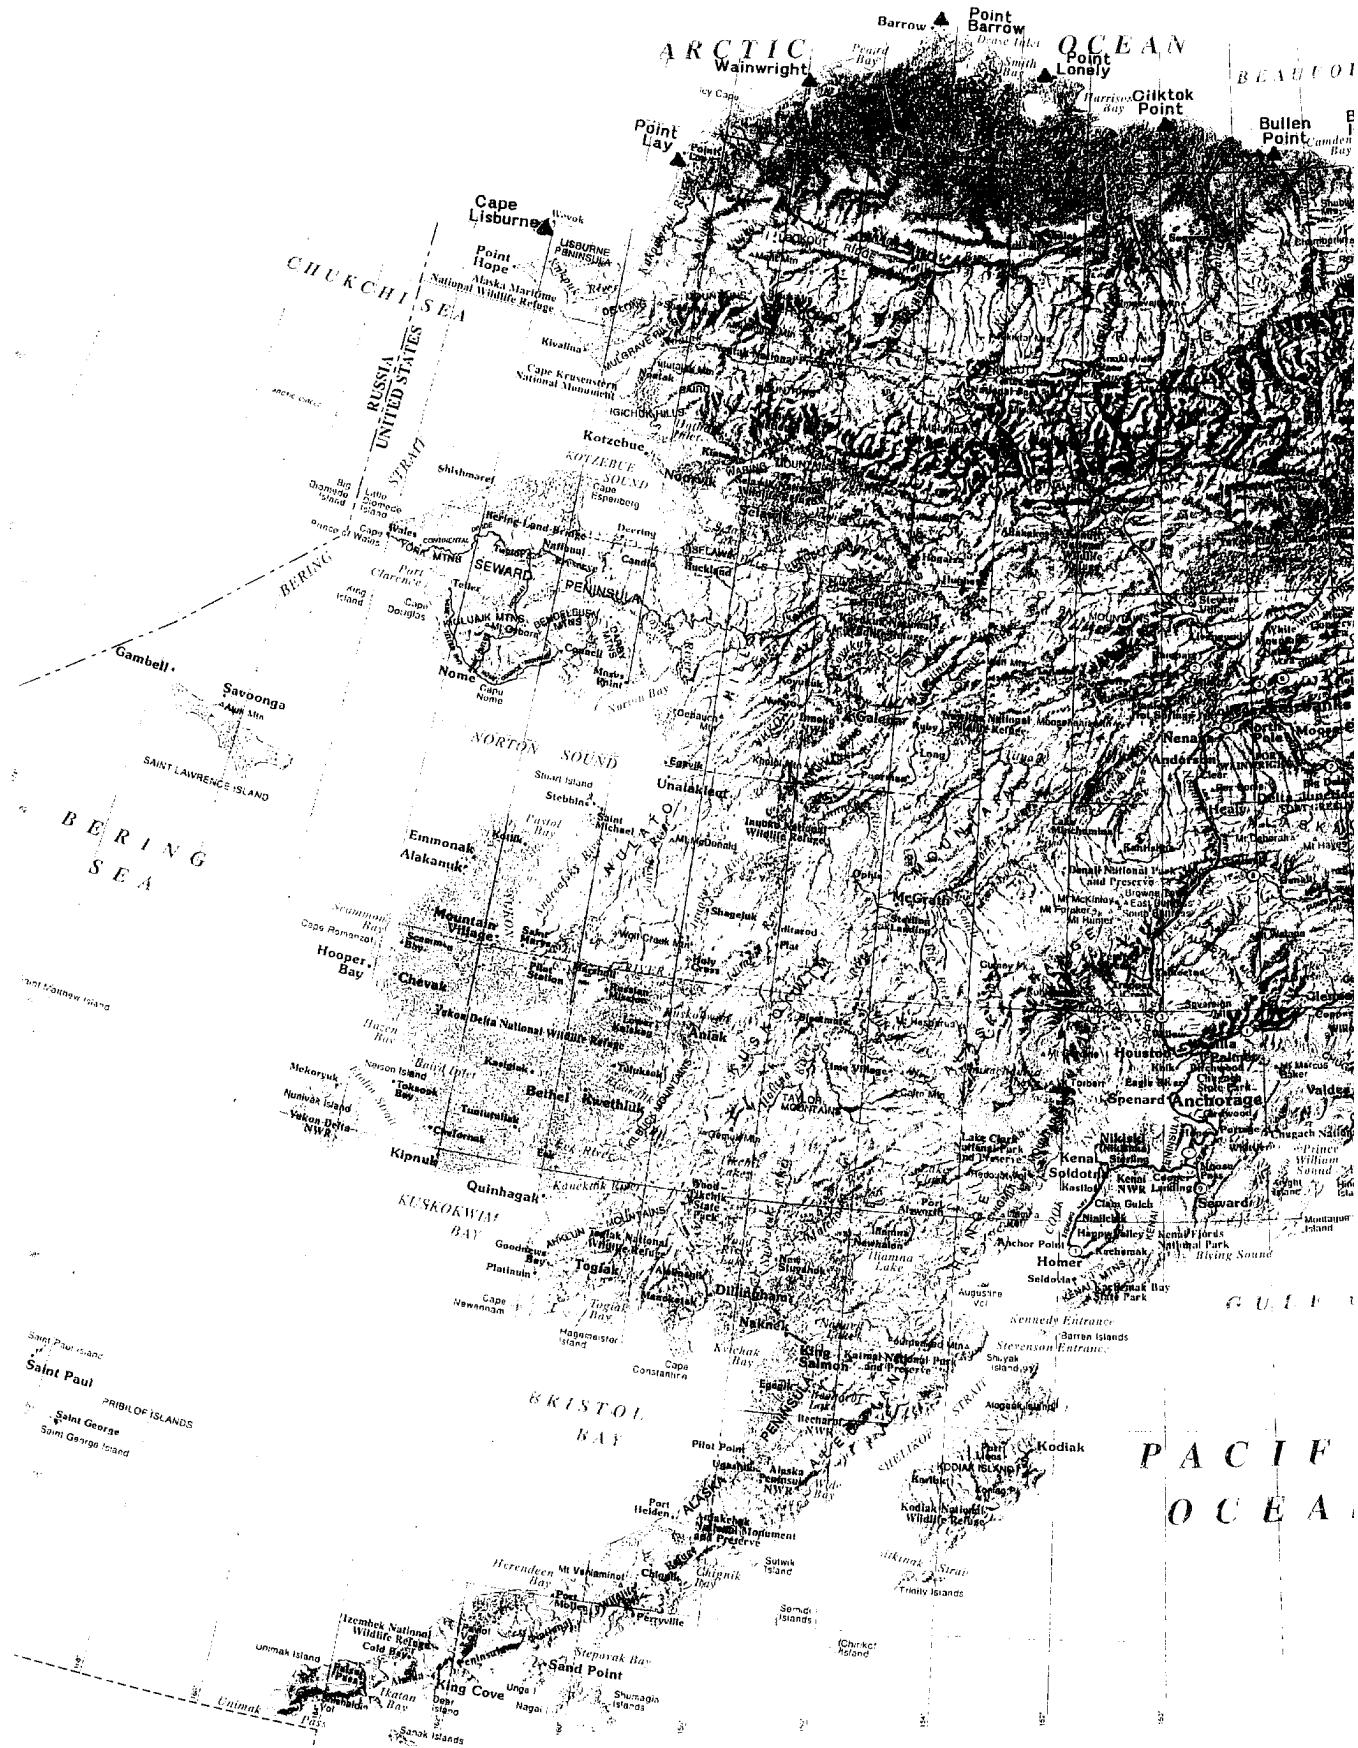

#### **1.1.1 Installation Background**

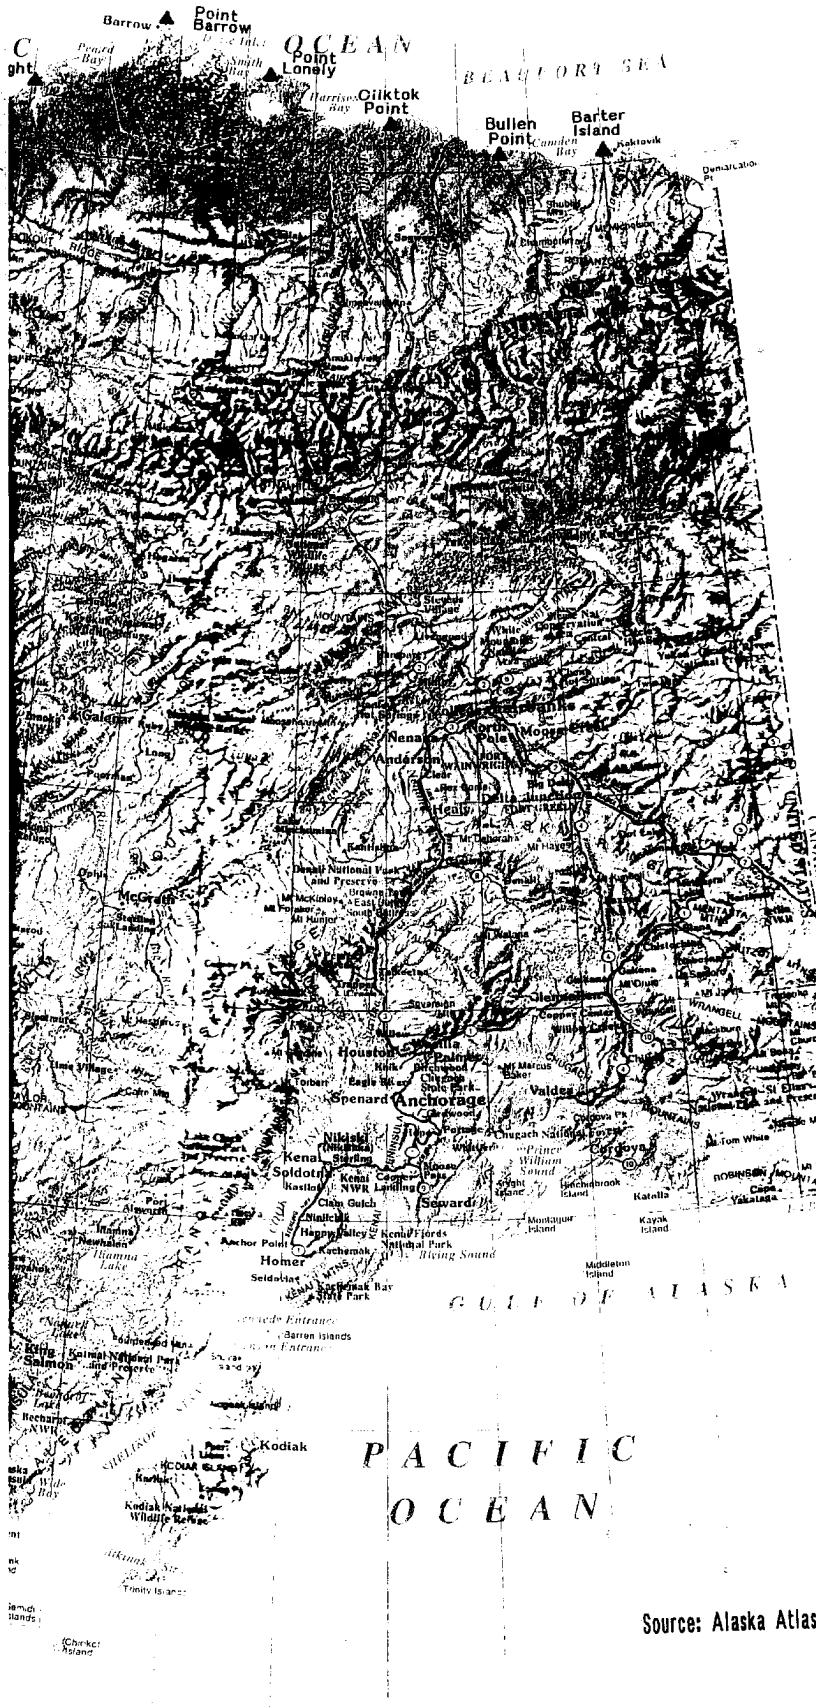

The Cape Lisburne radar installation consists of 1,125 acres of land along the shore of the Chukchi Sea and within the Alaska Maritime National Wildlife Refuge. It is located approximately 810 miles northwest of Anchorage and 570 miles northwest of Fairbanks. The general location of the Cape Lisburne radar installation is shown in Figure 1-1. An area location map is presented in Figure 1-2, and a site plan is provided in Figure 1-3.

The station is at latitude 68°52'N and longitude 166°15'W, and is accessible only by sea or air. Radar equipment is located at the Upper Camp, and support facilities for all station operations are located at the Lower Camp. The two camps are connected by a 3.9-mile gravel road. Point Hope, the nearest community, is located 35 miles to the southwest. There is no road connecting Point Hope and the Cape Lisburne installation.

The facility was one of the 31 original White Alice Communications Systems (WACS) built to establish an air defense system in Alaska. It was constructed in 1952 and 1953. The WACS began operation in August 1957. The WACS was deactivated in 1979 and replaced with a satellite earth terminal. Currently, four contract personnel at the station operate and maintain a Long Range Radar system located at the Upper Camp. Buildings at the Cape Lisburne installation are of traditional construction style. Support facilities in the Lower Camp include living quarters, a garage, a warehouse, inactive structures, and a 5,009 foot-long runway.

General and installation-specific descriptions of the geology, climate, hydrology, biology, demographics, and industrial activities are presented in the Cape Lisburne Remedial Investigation/Feasibility Study (RI/FS) report (U.S. Air Force 1995a).

A variety of past activities at the station may have resulted in environmental contamination. The United States Air Force (Air Force) is investigating and remediating actual and potential sources of contamination through activities conducted under the IRP.

There are five sites and one area of concern (AOC) at the Cape Lisburne Long Range Radar Station where IRP investigations have been initiated. These areas were identified based on the literature search of previous IRP investigations, the pre-survey and reconnaissance trips, and interviews with station personnel. Sampling and analysis were conducted at these six areas during the summer of 1993 as described in the RI/FS SAP (U.S. Air Force 1993). The areas include five sites: the Landfill and Waste Accumulation Area (LF01), White Alice Site (SS03), Spill/Leak #3 (ST07), the Upper Camp Transformer Building (SS08), and the Lower Camp Transformer Buildings (SS09). In addition an AOC, the Water Gallery (AOC3), was investigated. Sampling and analyses identified chemicals of concern at these sites, and it was determined that IRAs should be conducted at two of the sites, the Landfill and Waste Accumulation Area (LF01) and Spill/Leak #3 (ST07). Following are descriptions of the two sites at the station where IRAs were conducted.

### **1.1.2 Landfill and Waste Accumulation Area (LF01) Background**

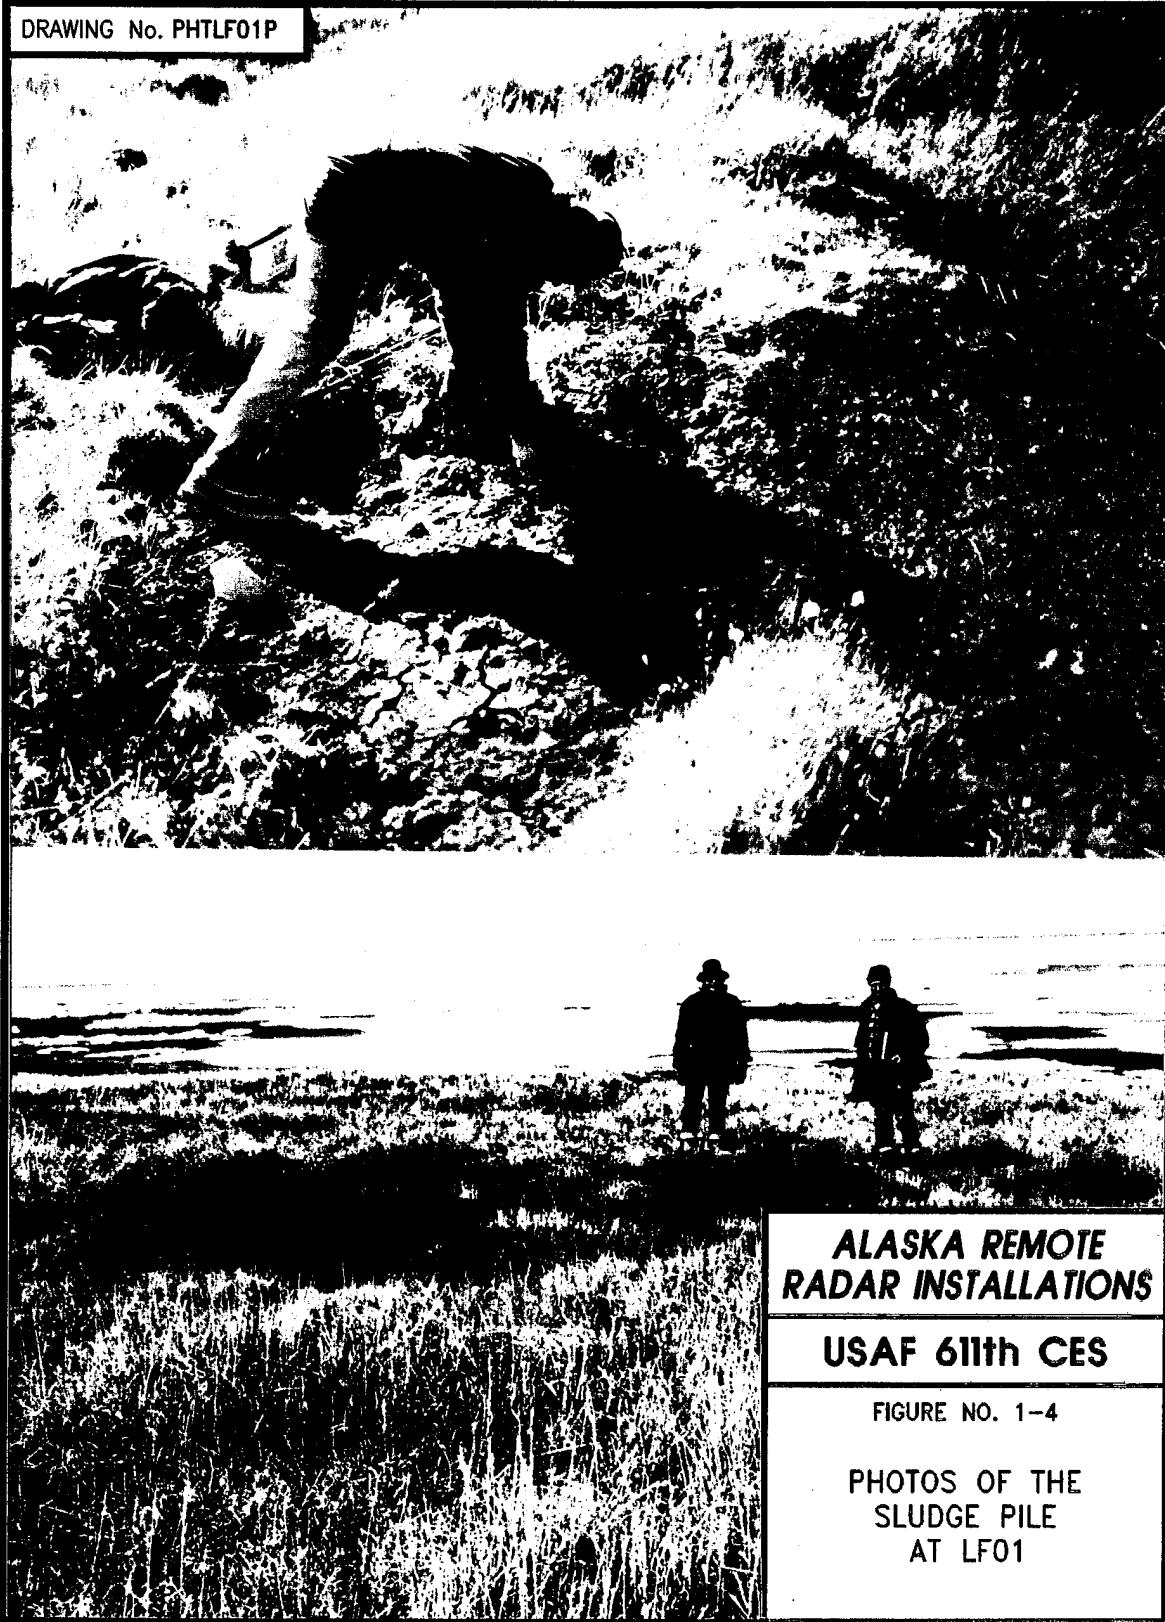

The Landfill and Waste Accumulation Area (LF01) site consists of three areas east of the main station and adjacent to the Chukchi Sea (Figure 1-3). These three areas, waste accumulation areas #1 and #2, and the landfill, are not clearly defined. The areas were used as landfills from 1952 to 1977. A general cleanup was performed at the site in 1977 and 1978. At that time, drums containing liquid wastes were shipped off site for disposal. Empty drums and other debris were reportedly buried in the accumulation areas and site landfill. A sludge pile covering approximately 200 square feet was identified during the 1993 RI on the west side of the site, approximately 50 feet north of the gravel road (Figure 1-4). Sampling and analysis conducted at the area detected residual range petroleum hydrocarbons (RRPH), benzene, toluene, ethylbenzene, and xylenes (BTEX), and volatile organic compounds (VOCs) in soil and water samples. Downgradient samples indicated low levels of contaminants were migrating from the sludge pile (Buried Drum Area).

### **1.1.3 Spill/Leak #3 (ST07) Background**

The Spill/Leak #3 (ST07) site is located in the area of the installation diesel tanks, adjacent to the Arctic Ocean and the east end of the airstrip (Figure 1-3). In August 1992 site personnel informed the Alaska Department of Environmental Conservation (ADEC) that diesel fuel had been observed seeping from the north hillside, adjacent to and downgradient of the two station diesel tanks. Test pits were dug and approximately 25 gallons of fuel were collected. Leak tests were conducted and site personnel could not determine the source of the leak (ADEC 1992). Visual observation at this location in 1993 during RI sampling activities showed a few gallons of diesel product in an approximately 2-foot by 5-foot polyethylene plastic-lined catchment area located

at the base of the hillside north of the diesel tanks (Figure 1-5). Sampling and analysis conducted during the 1993 investigations detected significant concentrations of diesel range petroleum hydrocarbons (DRPH), gasoline range petroleum hydrocarbons (GRPH), RRPH, BTEX, VOCs, and semivolatile organic compounds (SVOCs) in soil at this site.

## 1.2 PROJECT OBJECTIVES

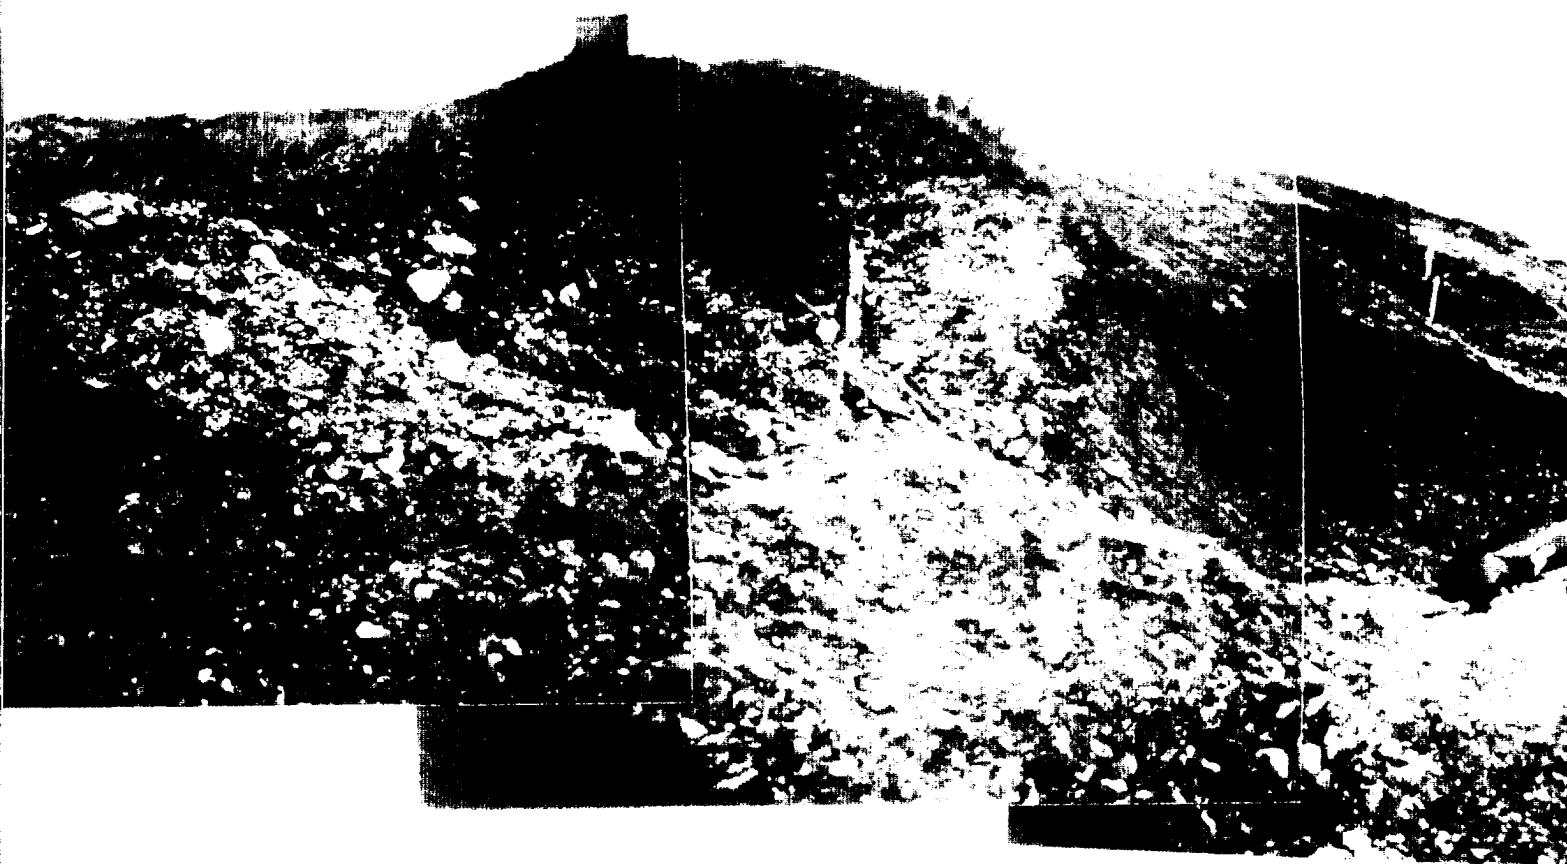

The objectives of this project were to remove and/or control the source contamination at portions of two sites through IRAs. These IRA sites were the Landfill and Waste Accumulation Area (LF01) and the Spill/Leak #3 (ST07).

The objective of the IRA at the Landfill and Waste Accumulation Area (LF01) site was to remove the buried drums of liquid and contaminated surface and subsurface soil to prevent the release and migration of contaminants from the site. The objective of the IRA at the Spill/Leak #3 (ST07) site was to collect any diesel product migrating from the site and to treat active layer water from the site that may contain dissolved constituents of diesel.

Two remediation activities were implemented as interim actions to prevent the migration of contaminants from the sites; they were not designed to be final cleanup actions at the sites. The remedial actions recommended for cleanup at these sites are reported in the Cape Lisburne RI/FS report (U.S. Air Force 1995a). Additional RI sampling was conducted in conjunction with IRA activities to characterize further the extent of contamination at the five sites at the installation. Results of these RI samples and previous RI sampling are provided in the RI/FS report.

## **2.0 INTERIM REMEDIAL ACTION AT THE LANDFILL AND WASTE ACCUMULATION AREA, SITE LF01**

An IRA was initiated in September 1994 at the LF01 site to remove what appeared to be a sludge pile/contaminated soils source area. The objective was to remove the source area to prevent contaminant migration downgradient into the natural tundra drainage towards the Chukchi Sea. Observations made during the 1993 RI conducted at the Cape Lisburne installation indicated that the sludge pile area was approximately 200 square feet and extended to a depth of as much as one foot. Contaminated soils in this area were excavated and placed in Department of Transportation approved containers during the September 1994 IRA for later disposal.

During hand excavation in September 1994 at the Sludge Pile, excavated areas filled with water and a thin layer of free-floating oily product. These organic liquids covered the vegetation they encountered, leaving a dark, saturated, peaty material. As the shallow excavation continued, six semi-crushed drums were exposed. After six cubic yards of contaminated soils had been removed and containerized, a geophysical survey was conducted using a metal detector. The survey indicated the presence of between 20 and 30 buried metal objects, presumably drums, in the immediate area. It became apparent that the source of black surface sludge was liquids that had leaked from the buried drums and floated to the surface during the seasonal periods when the ground was saturated with water. Henceforth, the sludge pile is referred to as the Buried Drum Area.

A continuation of the IRA was scheduled to remove the buried drums prior to the spring thaw, after which surface and active layer water would be likely to fill any excavation. Additionally, it was determined that the operation of heavy equipment while the ground was still frozen would do the least harm to the surrounding tundra. The IRA was initiated on 01 May 1995.

The following are descriptions of the excavation (Section 2.1), the containment cell (Section 2.2), and sampling and analyses (Section 2.3) associated with the contaminated materials removed during the May 1995 IRA at the site. A discussion of storage and disposition of waste materials is presented in Section 2.4. Locations of the Buried Drum (excavation) Area and containment cell where contaminated soils are temporarily stored are shown on Figure 2-1.

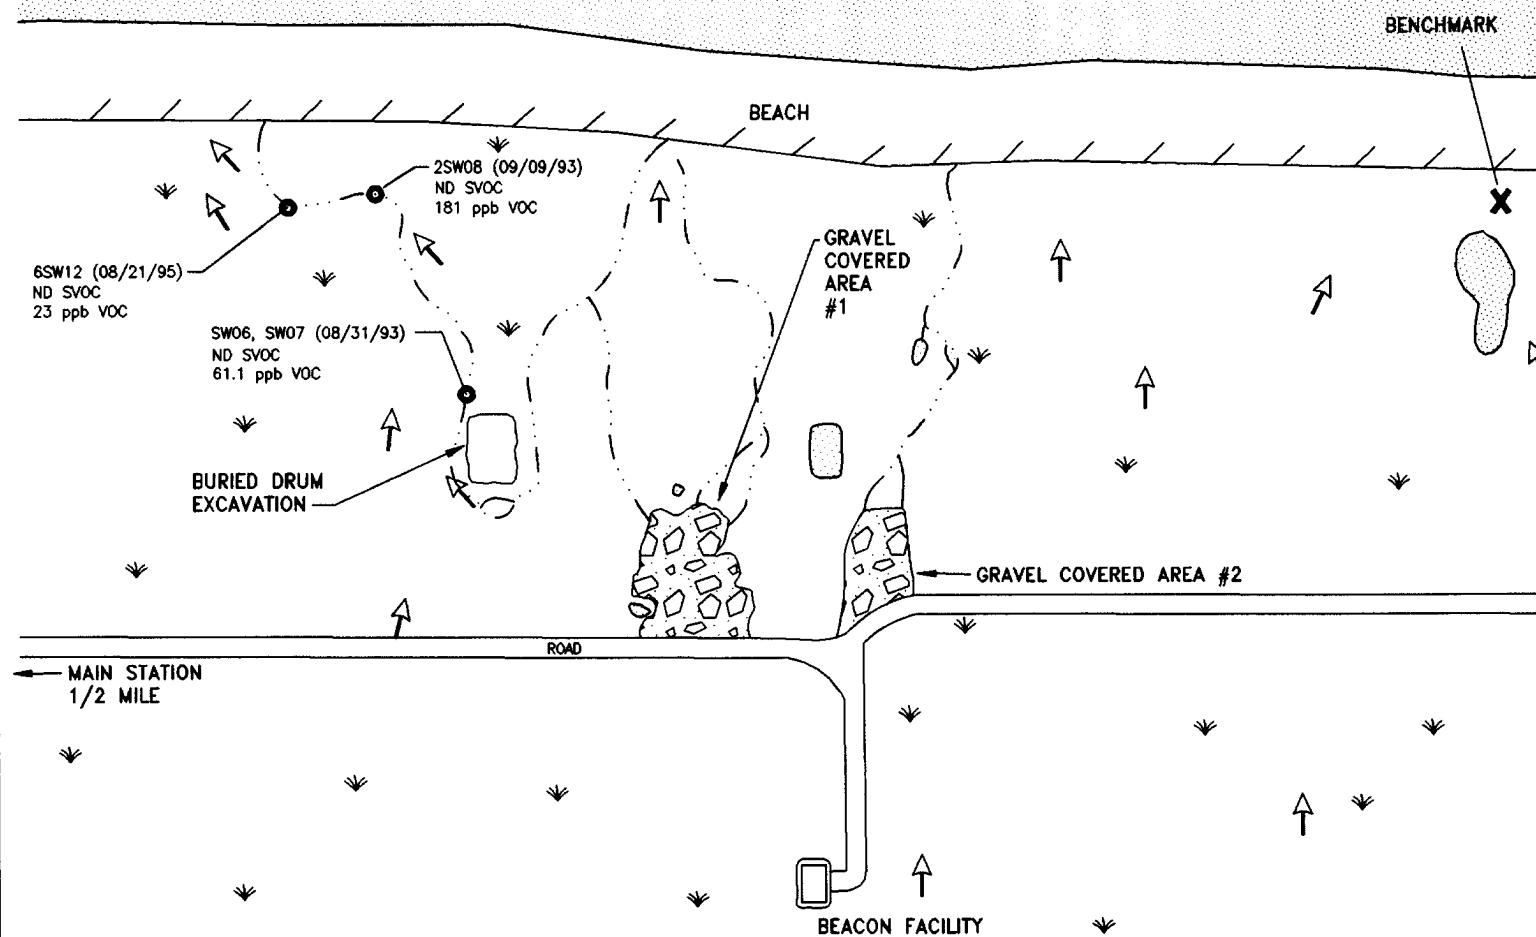

### **2.1 EXCAVATION**

The geophysical survey conducted in September 1994 indicated that buried drums were located beneath an area of approximately 25 feet by 35 feet (Photograph 1, Appendix A). On 03 May 1995 the excavation of the buried drums was initiated using the ripper on a D8 bulldozer to loosen the frozen soil and drums. As drums were exposed, any liquids present in the partially crushed and/or ripped drums were transferred into new drums using long-handled scoops. The loosened soils and drums were pushed up into piles and transferred to a lined containment cell (described in Section 2.2) using a large front loader (Photographs 2 through 9). A metal detector was used during excavation to assist in locating buried drums and determining the direction and depth of further excavation. Clearly defining buried drums and contaminated soils to be excavated, in order to minimize the volume of excavated materials, was greatly complicated by

the presence of buried metallic debris other than steel drums. On 07 May 1995 the excavation of drums was completed.

Approximately 100 drums were excavated over a period of five days. The buried drums had been stacked in clusters which accounts for the increase to approximately 100 drums excavated from the early estimate of 20 to 30 drums indicated by the geophysical survey. It was estimated that 50 of these drums were full of liquids and the rest were empty, full of ice, or contained ice and product. Approximately 450 gallons of liquids were recovered during the excavation. The majority of liquids appeared to be used motor oils; however, the contents of drums varied from heavy lubricating greases to almost clear liquids that may have been solvents. Liquids that could not be recovered and containerized in new drums were scooped up with soil using the heavy equipment and transported to the containment cell. When it appeared that the boundaries of the buried drums had been reached, the bottom of the pit was scraped down to frozen ground and all soils, liquids, and drums were removed. The completed excavation measured approximately 21 feet by 66 feet, with a maximum depth of approximately 6 feet. A drawing of the completed excavation is shown on Figure 2-2 and pictures of the excavation are shown in photographs 10 through 12.

Twelve soil samples were collected from the bottom and sides of the excavation (Photographs 11 and 12). All samples were analyzed for total petroleum hydrocarbons (TPHs) using field analytical methods. Three of the samples were also submitted to the laboratory for chemical analyses. Sample locations and analytical results are discussed in Section 2.3.

The liquids recovered during excavation were transferred into 55-gallon polyethylene drums suitable for shipping off site. Six drums of liquid, approximately 300 gallons, were labeled and sampled, and are temporarily stored in a vacant building at the installation. Approximately 150 gallons of sludge, water, and ice recovered during excavation activities were placed into the containment cell. Analytical results of the liquids sampled from the six drums are presented in Section 2.3.

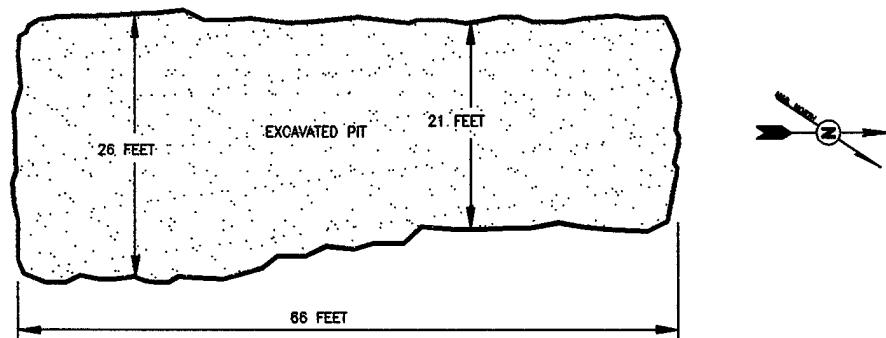

Once the results of field screening indicated that no significant levels of TPH remained in the soils of the excavated pit, 80 pounds of calcium peroxide were applied to the bottom and sidewalls of the pit (Photograph 10). This oxygenator was added to assist in the bioremediation of any residual contamination in soils in the bottom or sides of the excavation. Originally, the calcium peroxide was intended to be mixed with the excavation spoils to enhance bioremediation in the containment cell. However, the high contaminant concentrations in soils excavated eliminated bioremediation as an effective tool in the containment cell.

Backfilling of the pit was initiated on 08 May 1995 using a mixture of gravel and soil from a quarry site located in a hillside approximately one mile southwest of the main installation. Backfilled materials were compacted and leveled using the D8 bulldozer. The backfilling continued until the backfilled pit was approximately one foot higher in elevation than the original land surface (Photographs 13 and 14). Hand tools were used for the final leveling of the backfilled area, and on 11 May 1995 backfilling was completed.

During IRA activities in late June 1995, the backfilled area at the site was fertilized and seeded (see photograph 30). The area was fertilized with 20-20-10 (nitrogen-potassium-phosphorus) at a rate of approximately 350 pounds per acre. The tundra mix seed, 60 percent Bering hairgrass and 40 percent arctic fescue, was applied at a rate of approximately 40 pounds per acre. The fertilizer and seed were applied on 26 June 1995 using a broadcast spreader. By mid-August 1995 the seed had germinated, and the area had started to revegetate (see photograph 31).

## 2.2 CONTAINMENT CELL

Prior to initiating the excavation of the buried drums, a lined containment cell was constructed onsite at a gravel-covered area (closed landfill) located approximately 800 feet east of the Buried Drum Area (Figure 2-1). A D8 bulldozer and front loader were used to slope the gravel pad, excavate a sump area, and push up gravel berms around the sides and ends of the cell. The bottom of the containment cell was sloped at approximately a 1 to 100 (vertical to horizontal) ratio towards the sump on the long axis and at the same ratio perpendicular to the long axis centerline to ensure drainage of liquids into the sump. The containment cell and sump were lined with 23 mil black synthetic liner designated to perform in temperatures down to -65 degrees Fahrenheit (Photographs 15 through 18).

The final containment cell dimensions (inside) were approximately 20 feet by 105 feet. The length of the cell was extended from the original 70 feet to 105 feet to hold the additional volume of excavated materials (Photographs 19 and 20). Once the excavation was complete, the top of the excavated materials placed in the cell was leveled using the bucket of an excavator. Drums on the top surface of the contaminant cell soils were crushed to prevent protrusions of metal and potential tears in the cover of the cell. In addition, used carpet was placed over the top of the materials in the cell to reduce the potential for sharp objects to cut the top cover (Photograph 21). The top cover of the cell measured 40 feet by 120 feet and consisted of 23 mil black synthetic liner secured with gravel on the sides and ends. Excess cover material, approximately five feet on each side of the cell, was folded into the outside of the berm and covered with gravel. The sump, or west end of the cell, was secured with logs and a minimal gravel berm to facilitate access to the sump area.

Prior to closing the sump end of the cell, an attempt was made to collect the oily floating product that had drained into the sump; however, the product was only approximately an eighth of an inch thick and skimming was not successful. Prior to closing the cell, snow and ice excavated with the contaminated soils had melted, and water had collected in the sump to a depth of approximately six inches. Surface water from areas upgradient of the containment cell had seeped below the sump liner and was filling the excavated sump area. A pump was used to transfer the surface water from beneath the sump liner to the lined sump area (Photograph 22). The added weight and depth of the water in the sump prevented surface or active layer water from accumulating below the sump liner.

The lined gravel berms on the sump end of the cell are approximately five feet above the base of the sump, so liquids draining from the contained contaminated materials will back up into the main cell area, preventing the overflow of liquids from the sump.

A metal structural support beam was placed over the sump area to reduce the sag in the cell cover and to minimize the potential for water or snow to accumulate on the cover of the sump. Four aeration vents, constructed of PVC pipe and turbines, were placed in the sump end to provide transfer of air in and out of the cell and increase the evaporation of water that may collect in the sump (Photographs 23 and 24).

To minimize wind damage to the top cover of the cell, rope was criss-crossed along the length of the cell. Steel reinforcing bars were driven into the gravel just outside the lined cell to secure the rope. The entire containment cell was then circled with a rope fence to deter wildlife, such as caribou, from walking onto the top cover of the cell. Photographs 25 through 27 show pictures of the completed containment cell. Figure 2-3 shows the as-built containment cell.

Containment cell samples included five composite samples of the soil taken from three locations each along the length of the cell. The thin layer of floating product in the sump was also sampled. Sample locations and analytical results are discussed in Section 2.3.

The containment cell was inspected during late June 1995. The cover over the sump area of the cell was sagging due to the collapse of the metal structural support beam. The metal beam had buckled from the weight of rainwater that had accumulated on the cell cover. The cover on the sump was removed and three drums of liquid, a combination of free product and water, were removed from the sump of the cell. The depth of the free product on the sump was estimated to be 1/2 inch over approximately two feet of water.

The free product and water removed from the sump were sampled on 26 June 1995. The three drums of liquid are stored onsite with the six drums of liquid recovered during excavation activities. Analytical results for the free product and water samples are presented in Section 2.3

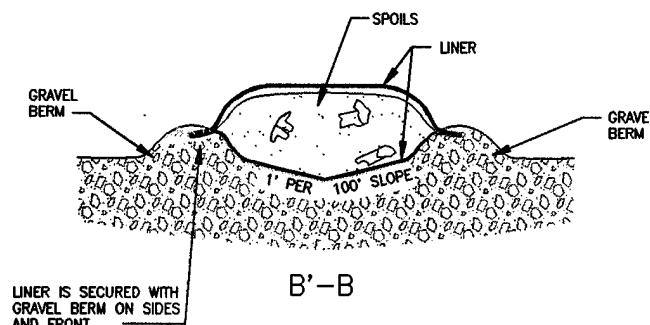

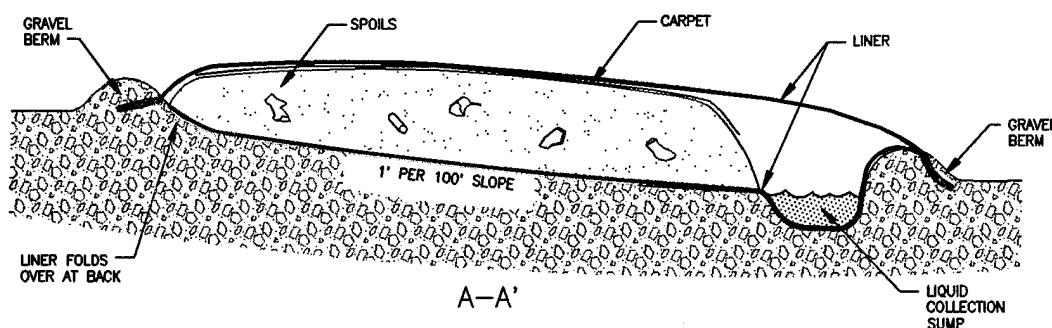

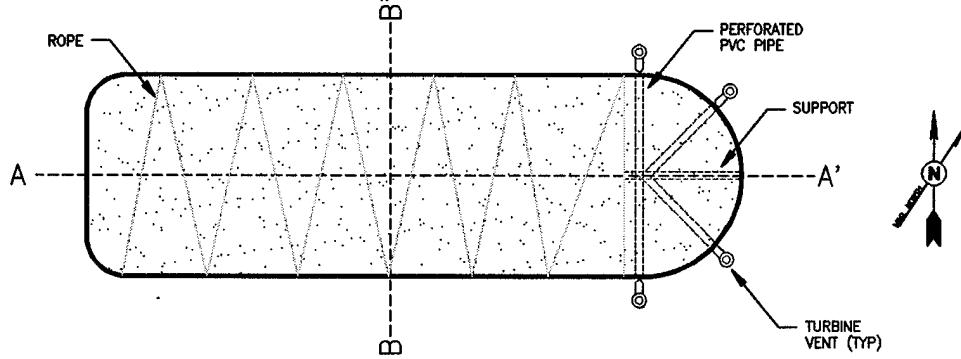

Large logs (driftwood) were used to build a new support for the cover over the sump area of the cell. One large log (approximately 12 inches in diameter) was used as the main support beam and cross beams, logs of approximately five-inches in diameter, were placed from the main beam to the sides of the sump area. A secondary liner cover was placed over the log supports, and the main (original) liner was placed over the sump. The edges of the liner were secured with gravel, and the ropes that cross-cross over the top of the cell cover were tightened. The work on the containment cell was completed on 28 June 1995.

Thawing and settling of the material in the containment cell, combined with high winds, caused wind damage to the top liner of the containment cell during late July 1995. Sufficient slack had accumulated in the top cover to cause flapping, eventually tearing the top liner. On 17 August 1995, a crew mobilized to Cape Lisburne to replace the top liner.

Repair of the top liner consisted of removing the old liner, removing sharp objects from the surface of the soil pile, pumping liquids out of the sump area of the cell, and installing a new 30 mil synthetic liner. To prevent liner flapping and wind damage, 1,500 sandbags were placed around and across the top of the new liner.

THIS PAGE INTENTIONALLY LEFT BLANK

Prior to installation of the new top liner, liquids from the sump area of the cell were pumped into 55-gallon drums. Ten drums of liquid were removed from the sump of the cell. The liquid removed was a mixture of oil and water phase, and it was estimated that 150 gallons (three drums) of floating oil product and 350 gallons (seven drums) of water phase liquids were removed.

As the sump was pumped, active layer water entered the subsurface depression beneath the sump liner and pushed the liner upward. As it appeared most of the liquids had drained from the soil pile, it was determined that the sump area was no longer needed as part of the containment cell. The bottom liner on the sump (east) end of the cell was freed from the gravel berm and pulled to the west approximately ten feet to the area of the cell containing soil and drums. Liquids beneath the liner consisted of water and a floating oil layer approximately one-eighth of an inch thick. Apparently a hole in the sump liner had allowed a small volume of oil to leak onto the water in the unlined sump depression. The oil and water were pumped from the sump depression and containerized in 55-gallon drums. A total of six drums, approximately 300 gallons, of liquid was removed from the sump depression. It was estimated that the liquids removed consisted of 20 gallons of oil phase and 280 gallons of water phase liquids. When all liquids were removed, sorbent pads were placed in the sump depression to collect any residual oil (see photographs 32 and 33). The east gravel berm was then pushed to the west approximately ten feet using a D7 caterpillar. The original bottom liner was secured over the berm with gravel (see photographs 34 through 36).

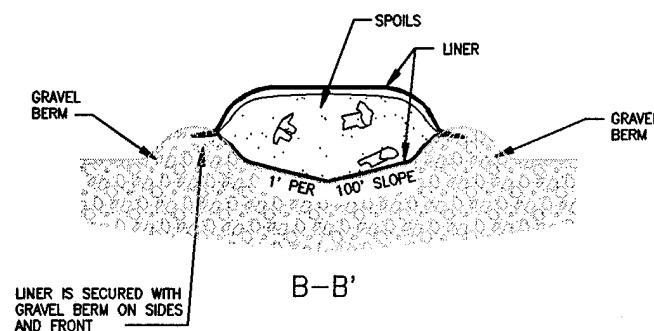

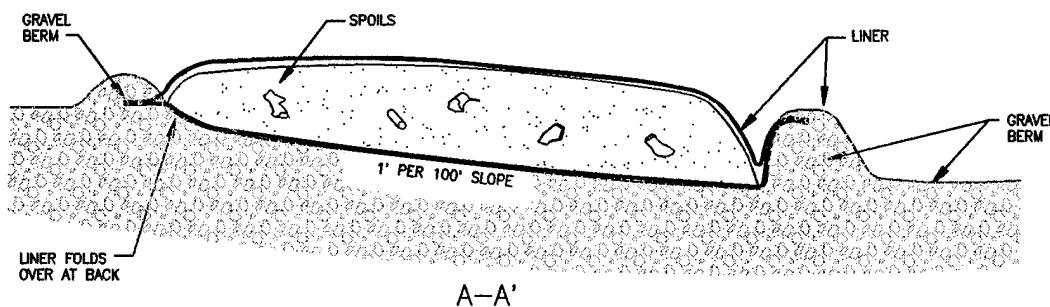

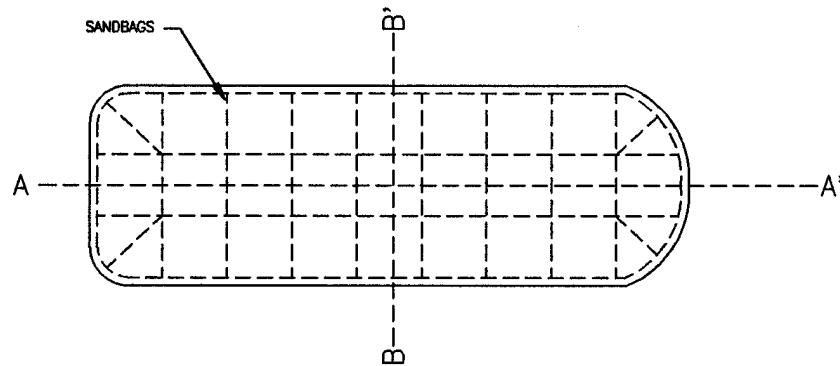

Prior to installation of the new top liner, six one-cubic yard containers of contaminated soil, hand excavated from the Sludge Pile/Buried Drum Area in September 1994, were emptied into the containment cell. The contaminated soils were from the same excavation as soils already within the containment cell. The new 30 mil top liner was installed over the containment cell and secured in place with sandbags (see photograph 36). The revised as built containment cell is presented in Figure 2-4.

It is not known whether removal of the sump area from the containment cell removed the portion of the bottom liner that was leaking; however, any residual oils are likely to remain bound to containment cell soils. If the bottom liner is leaking, the active layer water beneath the cell is likely to keep floating product in the liner of the cell. Permafrost contours roughly approximate the containment cell surface contours with its perimeter berm. Thus, any contamination below the liner should be held in the immediate vicinity of the containment cell. Upon remediation of the soils in the containment cell and removal of the containment cell bottom liner, the soils beneath the liner will require sampling and analysis to determine if the leak in the cell has caused any significant contamination. Based on visual observations, the amount of soil that may be affected is minimal compared to the volume of soil within the containment cell that requires remediation. It should also be noted that the containment cell is constructed on top of a closed landfill, and soils potentially impacted do not include any tundra or undisturbed areas.

\* Sample Identification Numbers are proceeded with LIS or LIZ for Cape Lisburne and LF01 for the site number. SW = surface water; W = waste; S = soil; and FP = free product. Sample numbers ending with a "x" indicate the sample was a subsurface soil sample collected at a depth of "x" feet below ground surface (e.g., 4S35-2 is soil sample number 35 collected at a depth of 2 feet below ground surface).

## 2.3 SAMPLING AND ANALYSES

This section describes sampling and analyses associated with the excavation area and containment cell at the LF01 site. A summary of the sampling conducted at each of these areas is presented in Table 2-1. The sampling and analyses conducted at these two areas are discussed separately in Sections 2.3.1 and 2.3.2.

### 2.3.1 Excavation Sampling and Analyses

During September 1994 IRA activities, a composite sample of the six cubic yards of excavated soils placed in one-cubic yard containers was collected during the shallow excavation at the

Buried Drum Area. This sample (LIS-LF01-3W04) was submitted for Waste Management Profile analyses. Results for this sample are presented in Table 2-2.

After excavation of the Buried Drum Area was completed in May 1995, twelve soil samples were taken from the base and sidewalls of the excavation and screened for TPH using a field test kit. The purpose of these samples was to confirm that all significant contamination had been removed from the excavation prior to backfilling. Additionally, three of the 12 samples were sent to the project's fixed-base laboratory in Anchorage, Alaska, where they were analyzed for VOCs, SVOCs, Polychlorinated Biphenyls (PCBs), GRPH, DRPH, and RRPH.

The field TPH analytical results for the 12 soil samples collected from the excavation area in May 1995 (sample LF01-4S34 through 4S45) are presented in Table 2-3. Table 2-4 presents the results of analyses on three of these same samples (replicate samples), LF01-4S35, 4S40, and 4S44, analyzed by the laboratory in Anchorage. Sample locations are shown on Figure 2-5.

During the August and September 1993 RI activities, surface water samples were collected from the drainage pathways downgradient of the Buried Drum Area. The water samples were SW06/SW07 (duplicate samples) and 2SW08. Total VOCs were detected in these samples at concentrations of 181 and 80.3 µg/L, respectively. (Total VOCs values are the sum of all VOCs detected in each sample). The same drainage pathway was sampled after removal of the surface sludge and buried drums from the excavation area (sample 6SW12). This post-IRA sample was collected on 21 August 1995. The total of VOCs detected was 23 µg/L. This indicates the surface water quality has improved in the drainage pathway. The drainage pathway during the August 1995 sampling was almost stagnant, and the VOCs detected may result from residual contaminants in the soil/sediments of the drainage pathway. The leaking drums and surface sludge have been removed from the site, so the water quality is expected to improve over time in the drainage pathway. Table 2-5 presents the compounds detected in the VOC analyses (8260) of these three surface water samples. Locations of these samples are presented on Figure 2-1.

Composite samples from each of the six drums of liquid collected during May 1995 excavation activities were sent to the Anchorage laboratory and submitted for Waste Management Profile analyses (samples LF01-FP1 through FP6). Results of these analyses are presented in Table 2-6.

### **2.3.2 Containment Cell Sampling and Analyses**

Once all excavated materials had been placed into the containment cell, five composite samples of the soils in the cell were collected. Each of the five samples was a composite of soils collected from the two sides and top of the soil pile. Figure 2-6 shows the locations of the materials in the cell that were composited into each of the five samples in May 1995 (samples LF01-4S46 through 4S50).

The five composite soil samples were analyzed by the Anchorage laboratory for VOCs, SVOCs, PCBs, GRPH, DRPH, and RRPH. Analytical results are presented in Table 2-7.

The oil phase liquids in the containment cell sump were sampled during May 1994. The analytical results for this sample (LF01-FP7) are presented in Table 2-6.

During June 1995 three 55-gallon drums of liquid, a mixture of free product and water, were collected from the sump of the containment cell. A water sample (LF01-5FP08) and a free product sample (LF01-5FP09) were collected at this time. These samples underwent Waste Management Profile analyses. Results are presented in Table 2-6.

#### 2.4 STORAGE AND DISPOSITION OF WASTE MATERIALS

The volume of contaminated soils within the containment cell is estimated at 186 cubic yards. Six cubic yards of contaminated soils removed from the surface of the Buried Drum Area (Sludge Pile) during the September 1994, and previously stored onsite, were put with containment cell soils in August 1995. In addition, approximately 25 gallons of soil are stored on site in a 55-gallon drum, the result of investigation-derived waste from the 1993 RI. Twenty-five drums of liquid were collected during IRA activities. One drum of spent activated carbon that was used to treat water from the decontamination pad is also stored with these drums. A summary of the waste stored onsite including media, location, volume, and associated sample numbers is presented in Table 2-8.

TABLE 2-3. EXCAVATION SAMPLES - FIELD TPH SCREENING RESULTS - MAY 1995

D Secondary dilution.  
E Identifies compound whose concentration exceeded the calibration range of the instrument for that specific analysis.  
U Undetected, analyte was not detected at the reported quantitation limit.

### **3.0 INTERIM REMEDIAL ACTIONS AT SPILL/LEAK #3 (ST07)**

This section describes the IRA at the Spill/Leak #3 (ST07) site, conducted to collect diesel potentially migrating in the subsurface just to the north of Diesel Fuel Arctic (DFA) tanks 1 and 1A. The majority of IRA activities at the site were conducted from 06 September through 13 September 1994. Startup and testing of the system, including installation of carbon treatment units to water effluent, were conducted during late June and mid-August 1995.

The objective of this IRA was to design, install, operate, and maintain a liquid petroleum recovery system to reduce the migration of diesel range petroleum from the hillside below POL tanks 1 and 1A to the drainage ditch and surface water at the toe of the hill. The recovery system is intended to operate for one to two years while remedial action and a more permanent solution are designed and implemented at the site.

#### **3.1 DESCRIPTION OF INTERIM RECOVERY SYSTEM**

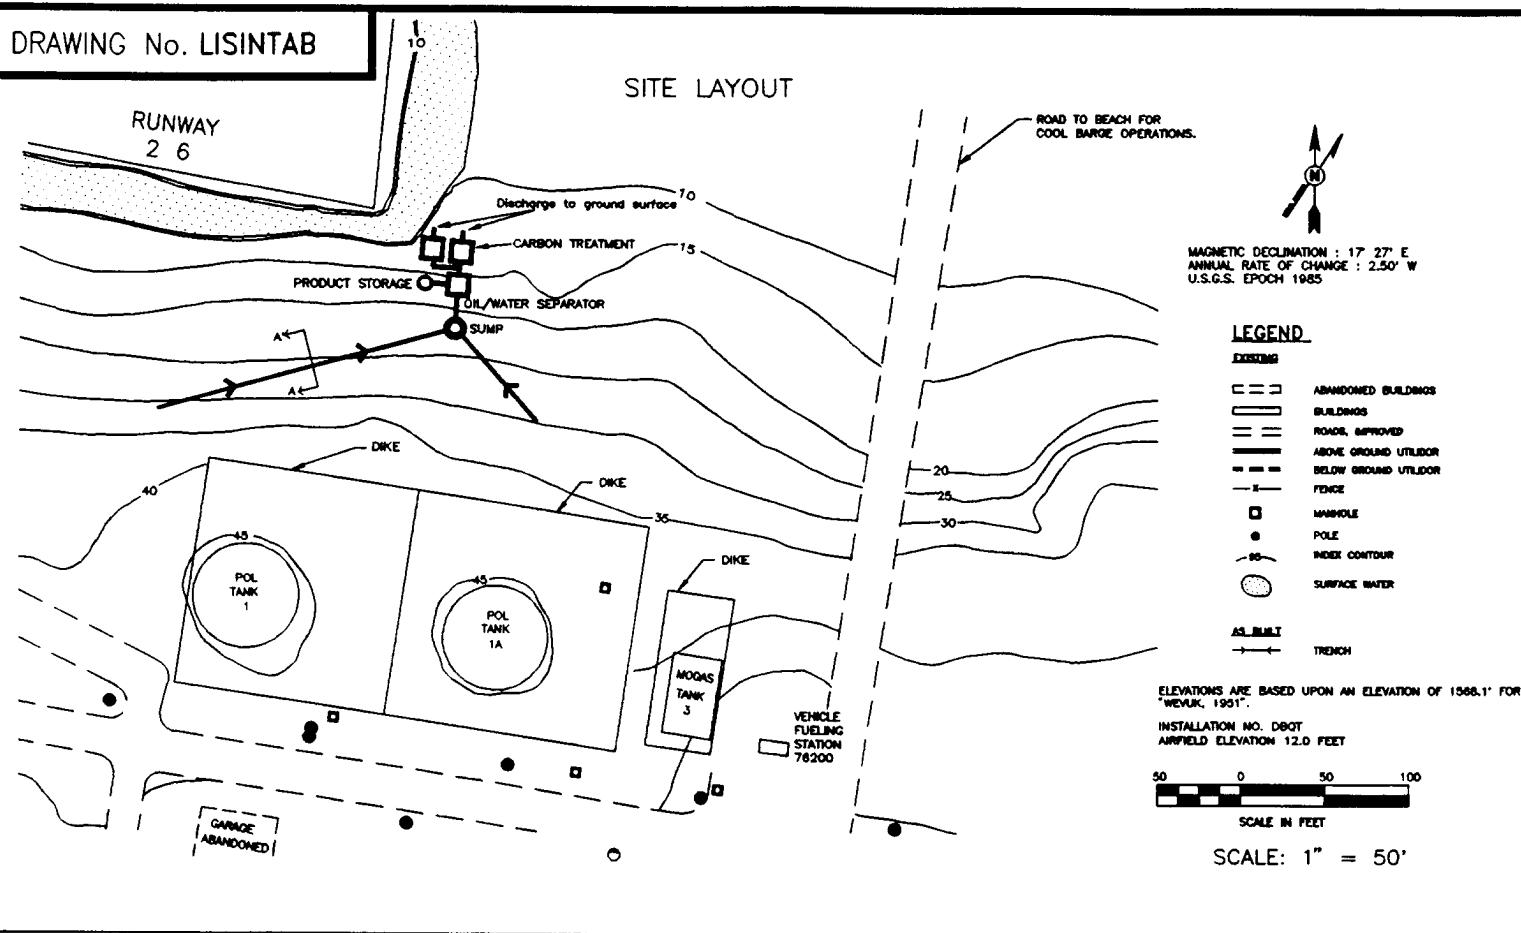

The interim remediation area is at the foot of a steep hill below DFA tanks 1 and 1A (Figure 1-5). Diesel is present in the active zone at the toe of the hill as a result of one or more unspecified leaks. The diesel can potentially migrate into the adjacent surface water body. Oil absorbent booms have been laid across the drainage channel to collect diesel reaching the water body. Sometime after the spill/leak was detected, a temporary diesel collection system was installed at the base of the hill, but it did not appear to be able to cope with large volumes of spring snowmelt and runoff. Presumably the diesel product floats on groundwater in the active zone on top of permafrost, which is present during the summer thaw. The depth to permafrost is estimated to be between four and seven feet during late summer. The ground is frozen during the winter months, immobilizing the diesel. Diesel migration is maximized during the spring thaw when the active zone is shallow, completely saturated, and with a significant volume of water moving through it. As summer continues and the permafrost melts further down, increasing the depth of the active zone, free hydrocarbons in the soil follow the water table down, "smearing" (adsorbing) onto soil particles, becoming less available for movement through the active zone.

The interim recovery system constructed consists of an interceptor trench installed near the toe of the hill that collects and drains active layer water and liquid petroleum into a centrally located sump (Figure 3-1). Fluids collected in the sump drain by gravity into an oil-water separator and then into a poly-tank for temporary storage of the diesel. Periodically, the diesel collected in the tank will be transferred to 55-gallon storage drums. The water effluent from the oil/water separator is piped into two 55-gallon drums of activated carbon, and then discharged to the ground surface.

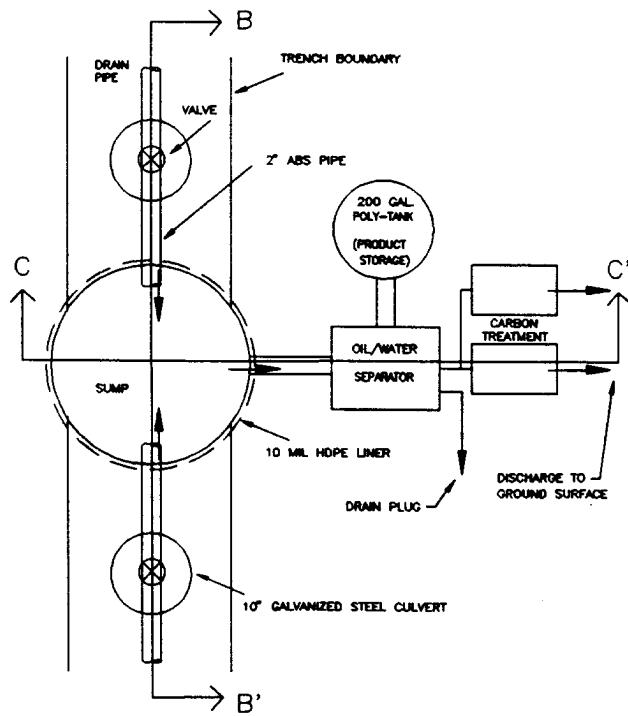

The interceptor trench is approximately 260 feet in length and between four and seven feet deep depending on the depth to permafrost at the time of construction. The trench is made up of two sections, the west trench is approximately 185' in length and the east trench is 74' in length. The east and west trenches were sloped at a rate of approximately 1:100 towards the central sump. High density polyethylene (HDPE) 10 mil plastic sheeting was used to line the trench, and two-

WATER COLLECTION AND  
TREATMENT SYSTEM

inch diameter perforated Duraplus pipe was installed on the plastic sheeting to collect and convey fluids. The base of the lined trench was backfilled with coarse gravel from an onsite quarry and then filled with previously excavated materials.

A circular sump was constructed near the center of the long axis of the trench in a hole excavated to approximately one foot below the bottom of the trench at that location. The sump was constructed of three-foot diameter corrugated, galvanized steel pipe. A galvanized steel plate was welded onto the base of the pipe to provide a watertight seal. The sump was insulated with fiberboard insulation to reduce the likelihood of upsetting the thermal equilibrium by creating a temperature gradient across the wall of the sump. The pipes from the interceptor trenches gravity drain into the sump, and two two-inch gravity drains convey fluids from the sump to the oil-water separator positioned below the sump. The oil (diesel) will be collected in a 200 gallon polytank that will be emptied as necessary.

### **3.2 SYSTEM CONSTRUCTION**

The interim product recovery system was constructed in several phases. The first phase consisted of laying out the approximate location of the trench, sump, and oil-water separator. This was done by staking the position of the sump, oil-water separator, and the two trench branches on the ground. The position of the oil-water separator was selected so that the base is approximately two feet above the elevation of the surface water. The sump was positioned directly up slope from the oil-water separator such that the pipe from the sump to the separator would have at least a one percent slope. (Photograph 37, 39, and 40 in Appendix A).

The second phase was to excavate test pits on 30-foot centers along the length of the trench. These test pits served two purposes: first, the soil and active layer water conditions were observed in each location to check for indications of liquid petroleum; second, the elevation of the top of permafrost was measured at each location. These data were used to finalize the position of the trench. The final trench was long enough to bracket the most distal test pits where indications of free product or soil staining were observed. The elevation of the top of permafrost was surveyed and posted on a base map to verify that the necessary gradient was established to drain the trench towards the sump.

The third construction phase consisted of the bulk of the system installation. The east and west trenches were excavated to their finished depth, starting from each end point and working towards the central sump. After a section of trench had been excavated, a strip of HDPE liner was lowered into the trench and positioned so that one edge was on the bottom and uphill edge of the trench. The rest of the liner was draped across the bottom of the trench, and up the downhill edge of the trench where it was secured until the trench was backfilled. (Photograph 38).

Next, the Duraplus drain pipe was glued together at the surface, wrapped with filter fabric, and lowered into the excavation. After the pipe was in the trench, it was covered with a minimum of six inches of coarse gravel from the installation quarry. After placing the gravel, excavation spoils were used as fill until the trench was filled to within approximately six inches of the original grade.

At that point, any excess HDPE liner was extended across the trench in the uphill direction to impede direct infiltration of snowmelt and runoff into the trench. The liner was covered with at least six inches of soil to protect it from the wind.

A rectangular area was excavated for the sump to a depth of approximately one foot below the elevation at which the drain pipes approach to permit drainage into the sump. A trench was also excavated for pipes between the sump and the oil-water separator. Finally, a level gravel cover was constructed downgradient of the sump for the oil/water separator, product storage tank, and activated carbon treatment units. (See photographs 37 through 40 that show the collection and treatment system during construction.)

### **3.3 INITIAL SYSTEM STARTUP AND CHECKOUT**

After the system had been fully constructed an initial system checkout was conducted. These tests were designed to measure water and product flow rates and to collect water samples that were subsequently used in order to gain data to design a water treatment system.

First, the oil-water separator was filled until water began to drain from the water effluent pipe. Next, the sump and oil/water separator were checked to estimate the rate of inflow and to see if a petroleum sheen was apparent. Only a very minor sheen was observed. The flow rate was estimated by suspending a bucket with a known capacity from the water discharge part of the oil/water separator. The estimated flow rate was 12 gallons per minute. During the system startup, all effluent from the system was collected in 55-gallon drums. Approximately 300 gallons of water were containerized, including the water drained from the oil/water separator after completion of the startup test.

A water sample (3SW06) was collected on 13 September 1994 from the water effluent sampling port on the oil-water separator. This sample was submitted for laboratory analysis to determine the concentration of dissolved petroleum constituents. The sample was analyzed for DRPH, VOCs (8260), and SVOCs (8270). The analytical results are presented in Table 3-1.

Analytical results indicate that water collected and discharged by the system contained approximately 7 ppm DRPH. Low levels of VOCs and SVOCs detected consisted of components of diesel. Based on the flow rate and concentrations, a water treatment system was designed to treat the effluent from the oil/water separator.

In late June 1995, two activated carbon adsorption units were piped in parallel into the effluent from the oil/water separator. The water in the sump was still frozen, and no influent or effluent samples could be collected. All fittings on the system were connected, and the system was prepared for operation. In addition, the areas disturbed by the construction at the site were seeded and fertilized at the same application rates as used at the backfilled area at site LF01 (see Section 2.1).

On 17 August 1995, the operation of the collection and treatment system was observed and inspected. The oil skimmer within the oil/water separator was adjusted, and the carbon units

<sup>a</sup> Influent to oil/water separator.

<sup>b</sup> Effluent from carbon units.

NA Not analyzed.

piped into the effluent line were placed in a horizontal position to reduce back pressure. Photographs 41 and 42 (in Appendix A) show the operating treatment system. No diesel odor or sheen was detected in any of the treatment system components during the inspection.

Samples were collected on 17 August 1995 from the influent (6SW07) into the oil/water separator and the effluent (6SW08) from the carbon units. The water samples were analyzed for petroleum hydrocarbons [United States Environmental Protection Agency (EPA) 418.1] and BTEX (EPA 602 18AAC78). No contaminants were detected in either the influent or effluent samples. Analytical results are presented in Table 3-2, and complete laboratory analysis reports are presented in Appendix B.

### 3.4 OPERATION AND MAINTENANCE

The system is designed to require minimal maintenance. The system will be monitored to determine if all components are operating properly. The amount of free product (diesel) collected

in the product storage tank will be measured. If required, the storage tank contents will be transferred to a 55-gallon drum.

It is recommended that, during early summer 1996, samples of the influent entering the system and effluent from the carbon units be collected and analyzed for TPH and BTEX.

Based on the results of the water samples and the amount of diesel product, if any, recovered, a determination will be made as to whether to continue operation of the system. If diesel product sheen, or constituents of diesel are detected in the influent sample or in any system components, operation will be continued. Sample results will determine if or when the carbon units should be replaced.

At the end of the 1995 operating season (mid-September) the system was winterized by closing the inflow valve to the oil/water separator, allowing the water to bypass the treatment system, and draining the oil/water separator and carbon units.

## **4.0 CONCLUSIONS AND RECOMMENDATIONS**

This section presents the conclusions and recommendations for the IRAs conducted at the Landfill and Waste Accumulation Area (LF01) site and the Spill/Leak #3 (ST07) site.

### **4.1 IRA AT LANDFILL AND WASTE ACCUMULATION AREA (LF01)**

The IRA at the Landfill and Waste Accumulation Area (LF01) site, was conducted to contain liquid contaminants leaking from buried drums and migrating from the Sludge Pile/Buried Drum Area of the site. Source areas of contamination were observed at the site during the RI activities in 1993. RI sampling and analyses in August and September 1993 confirmed that low levels of contamination were migrating from the site and affecting downgradient soils/sediments and water quality.

Hand excavations were conducted during September 1994 at the Sludge Pile/Buried Drum Area. The excavation was completed at the site using heavy equipment during May 1995. Approximately 100 drums were removed from the excavation; the total volume removed from the excavation was estimated at 186 cubic yards.

Prior to backfilling the excavation with clean backfill, twelve soil samples were collected from the bottom and sidewalls of the excavation. Samples were field analyzed for TPH, and results indicated no significant contamination. Three split samples that underwent laboratory analyses, however, did contain levels of contaminants that are considered significant. The reason for the discrepancy between the field and laboratory analyses is likely due to the complex mixture of contaminants found in the excavation. Field samples were analyzed using a Hanby kit which compares reaction matrix, color, hue, and intensity to photographs of standardized results of tests done on known concentrations of discrete petroleum hydrocarbon types (i.e., gasoline, diesel, or crude oil). In situations such as the Buried Drum Area where the contaminants included a wide range of compounds (used motor oils, heavy lubricating grease, and solvents), there are no valid standards to compare the test results against. Based on the laboratory results, the subsurface soils surrounding the excavation area contain petroleum hydrocarbons (mainly RRPH), VOCs that are common components of these hydrocarbons, and some solvents. While the laboratory analyses showed significant levels of the above contaminants remain in the excavation, these levels average two orders of magnitude less than those found in the soils which were removed. The contaminants remaining in the excavation are likely a relatively thin layer which diffused into the frozen walls and bottom of the excavation from the much higher concentrations in spoils during the removal process.

Several problems were identified during the excavation and containment of drums, liquid waste, and contaminated soils. First, the size and volume of the area requiring excavation was significantly greater than anticipated. A complete electromagnetic survey (i.e., ground penetrating radar) should have been conducted at the site prior to initiating the excavation. Second, the frozen ground did not allow the removal of intact drums. Most of the drums were ripped open by the heavy equipment during the excavation process. An alternate excavation method should be used at the site in the removal of other potential buried drum areas (e.g., steam knives could

be used to thaw soils surrounding the drums so the drums and liquids in the drums can be removed intact. Third, the containment cell bottom liner should have been constructed of at least 30 mil liner material or two liners with a clay layer in between, and materials (ripped drums, ice, rocks) should have been put into the cell more carefully to avoid tears or holes in the liner. Fourth, the top liner covering the containment cell should originally have been anchored in place with sandbags to prevent wind damage.

It is recommended that prior to any further excavation at the site the remedial action selected for the excavated material, offsite or onsite treatment, be prepared to handle all wastes generated so that temporary onsite storage (i.e., containment cell) of waste materials is not required.

The remedial action alternative currently recommended at the site is thermal desorption of contaminants from soil and offsite incineration of the concentrated condensate. The soils within the containment cell will be remediated along with soils at the site contaminated with PCBs, solvents, and petroleum hydrocarbons. During subsurface sampling at gravel area #1, drums were encountered at a depth of approximately two feet. It is very likely that gravel area #1 and gravel area #2 contain buried drums; a survey conducted with a metal detector indicated that metal objects were buried in these areas. Remedial design activities should be conducted at the Landfill and Waste Accumulation Area to determine the area of the buried drums at these gravel areas. In addition, a complete electromagnetic survey of the site may discover other areas where buried drums are located. Details regarding contaminated areas at the site and recommended remedial alternatives are provided in the Cape Lisburne RI/FS report (U.S. Air Force 1995a).

#### **4.2 IRA AT SPILL/LEAK #3 (ST07)**

The IRA at the Spill/Leak #3, site ST07 was conducted because diesel fuel was observed in a temporary collection area at the base of the hillside during September 1993. During IRA construction activities in September 1994, diesel odor and sheen were observed. A water sample taken of the effluent from the oil/water separator in September 1994 contained approximately seven parts per million of DRPH. This sample was taken two days after the interceptor trench was completed and subsurface soils at the site had been excavated and backfilled.

Influent and effluent samples collected in August 1995 did not contain petroleum hydrocarbons or BTEX above the detection limits. In addition, there were no obvious signs (i.e., odor, sheen) of diesel within the collection and treatment system. It appears the residual diesel contamination at the site is bound to site soils and diesel product and/or dissolved constituents of diesel are not currently migrating from the site.

Based on the observations and data collected during the IRA, Risk Assessment, and RI/FS reports (U.S. Air Force 1995a and 1995b), it is recommended that the remedial alternative selected for the site, natural attenuation be implemented at the site. This remedial alternative is recommended because there does not appear to be any ecological or human health risk associated with site contaminants and sampling has confirmed that contaminants are not migrating from the site. Sampling and analyses of the influent and effluent from the treatment system should be conducted during the spring thaw to confirm conditions at the site have not

changed and that no contaminants are being discharged. The collection and treatment system (french drain, oil/water separator, and carbon filters) should continue to be operated prior to, and during, scheduled tank replacement actions at the site to ensure contaminants do not migrate from the site.

**APPENDIX A**  
**IRA PHOTOGRAPHS**

**Photograph 1:** Tall stakes delineate the four corners of the buried drum area prior to initiating the excavation.

**Photograph 2:** The ripper on a D8 bulldozer was used to loosen the frozen soil and drums.

**Photograph 3:** A front loader with a large capacity bucket was used to scoop up excavated drums and soil.

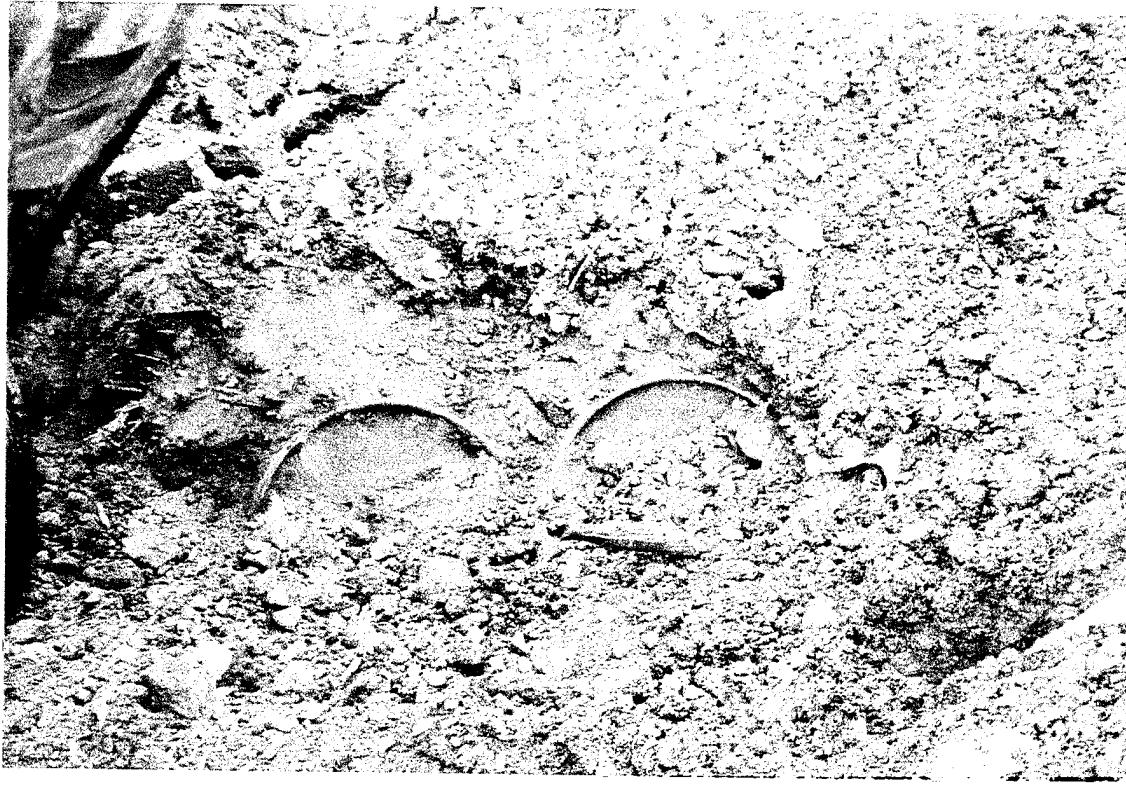

**Photograph 4:** As buried drums were exposed the contents were transferred to new drums.

**Photograph 5:** Five-gallon buckets were used to transport the recovered liquids to new 55-gallon drums at the staging area.

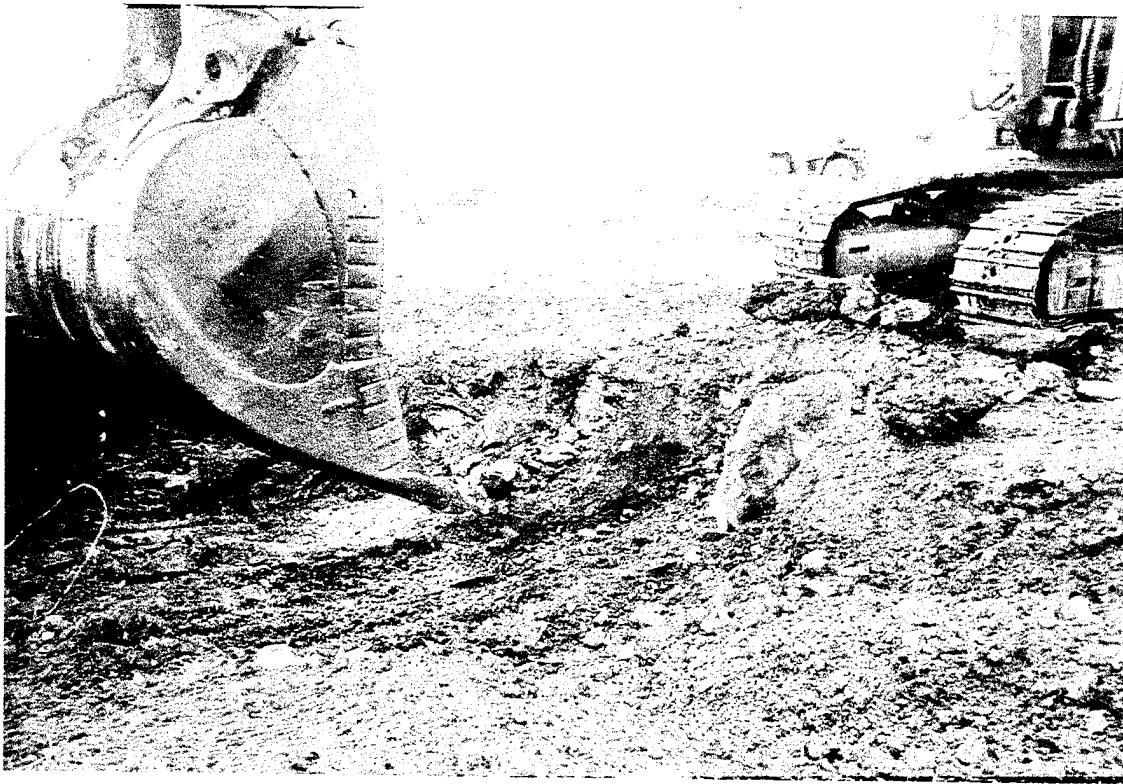

**Photograph 6:** Approximately 50% of the drums contained liquid, others were empty or filled with ice.

**Photograph 7:** These drums were located at a depth of approximately 4.5 feet below ground surface.

**Photograph 8:** An excavator was used to remove drums and soils from the pit.

**Photograph 9:** The large bucket of the excavator was able to excavate specific areas in the pit where the metal detector indicated metal objects were present.

**Photograph 10:** Approximately 100 drums were removed from the completed excavation. The light color in the pit is the calcium peroxide that was added prior to backfilling.

**Photograph 11:** Sidewall (Photo 11) and bottom (Photo 12) samples were collected and tested for TPH prior to backfilling.

**Photograph 12**

**Photograph 13:** A view to the south of the backfilled excavation.

**Photograph 14:** A view to the north of the backfilled excavation. The excavation is located approximately twelve feet west (left) of the surface water drainage.

**Photograph 15:** The containment cell was sloped and bermed to facilitate drainage to the sump.

**Photograph 16:** The sump is located on the east end of the cell.

**Photograph 17:** An inclinometer was used to assure the required slope.

**Photograph 18:** The bottom liner was put in place and secured with gravel.

**Photograph 19:** As the containment cell was filled it was extended 25 feet in length to hold the additional volume of material excavated.

**Photograph 20:** The top of the spoils pile was leveled prior to installation of the containment cell cover.

**Photograph 21:** Prior to installing the containment cell cover, used carpet was laid over the spoils pile to minimize the potential for sharp objects to puncture and tear the cover.

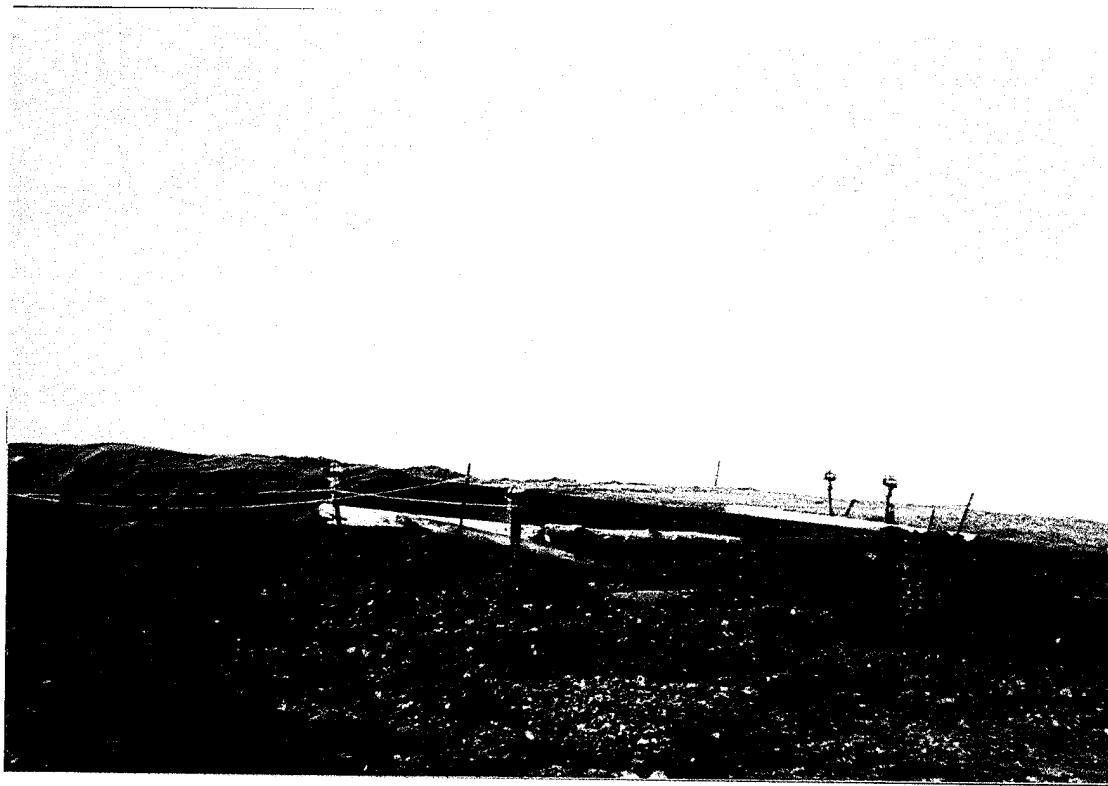

**Photograph 22:** Surface water from upgradient of the containment that had seeped under the sump liner was pumped from the unlined to the lined area of the sump.

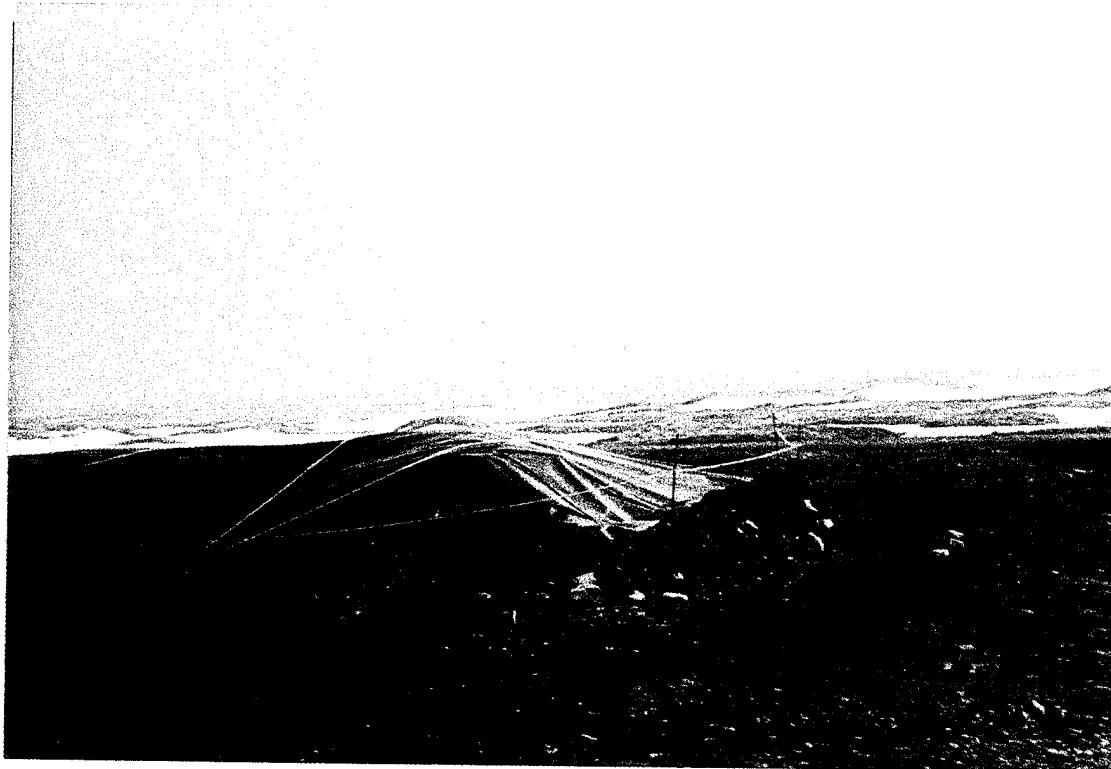

**Photograph 23:** Four turbine vents were constructed in the sump (east) end of the containment cell (Photos 23 and 24).

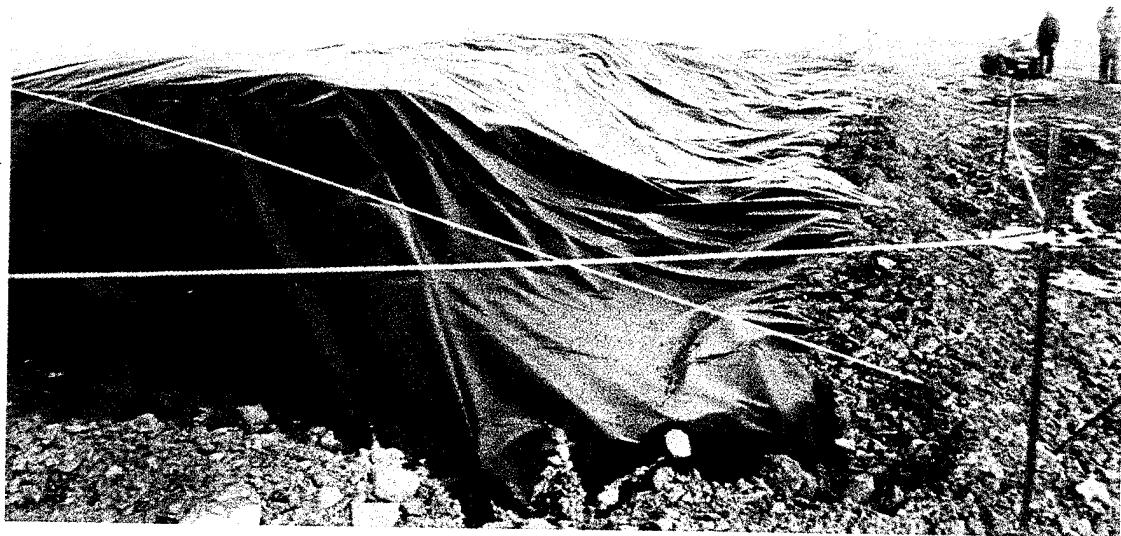

**Photograph 24**

**Photograph 25:** The sump (east) end of the completed containment cell.

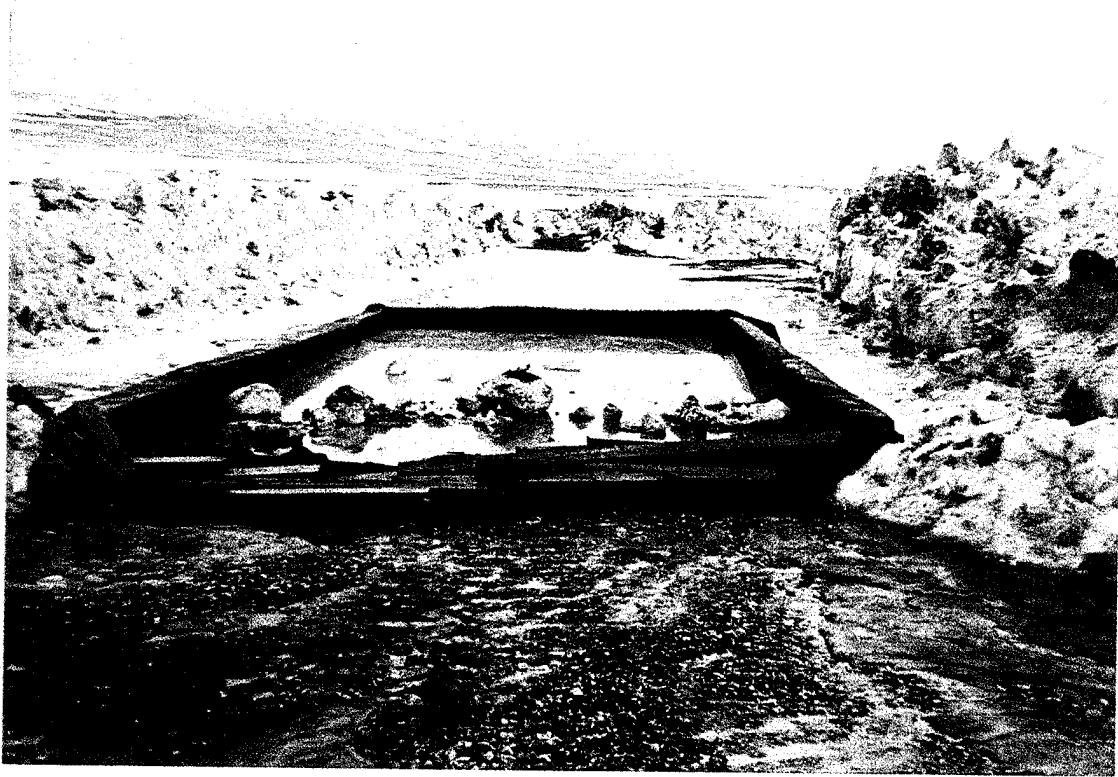

**Photograph 26:** The west end of the completed containment cell.

**Photograph 27:** A view of the south side of the containment cell showing the ropes that criss-cross the cell cover.

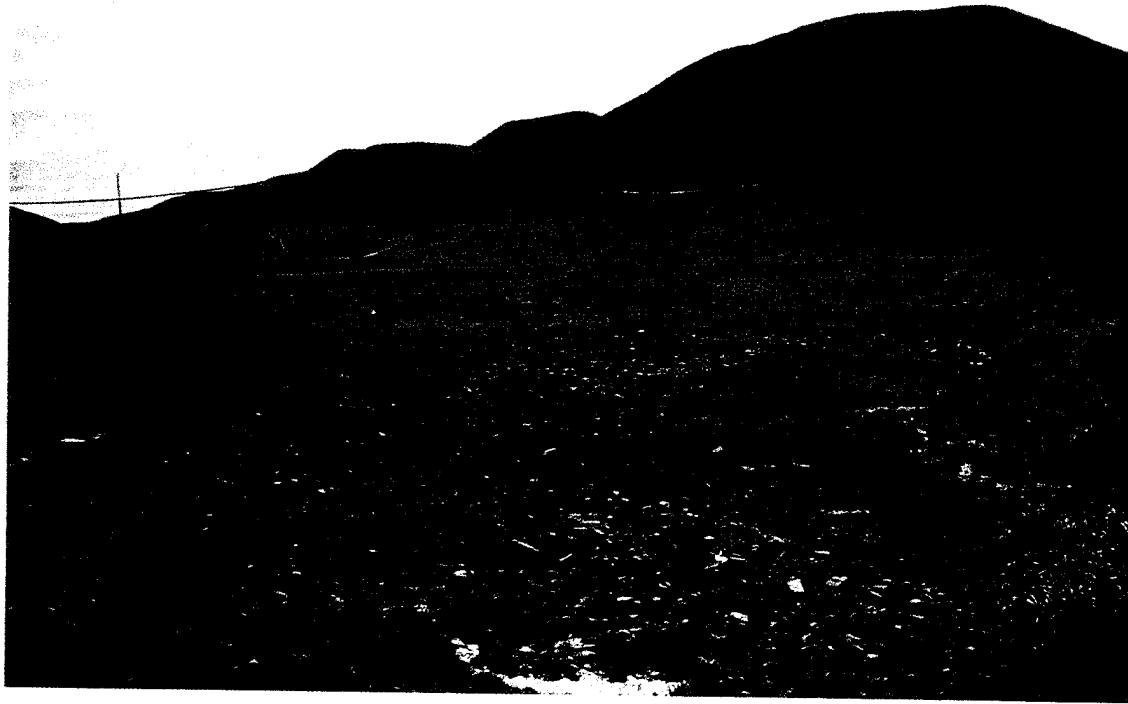

**Photograph 28:** Large equipment was decontaminated using a steam cleaner.

**Photograph 29:** The decontamination water was contained in a bermed area approximately 26 feet by 20 feet.

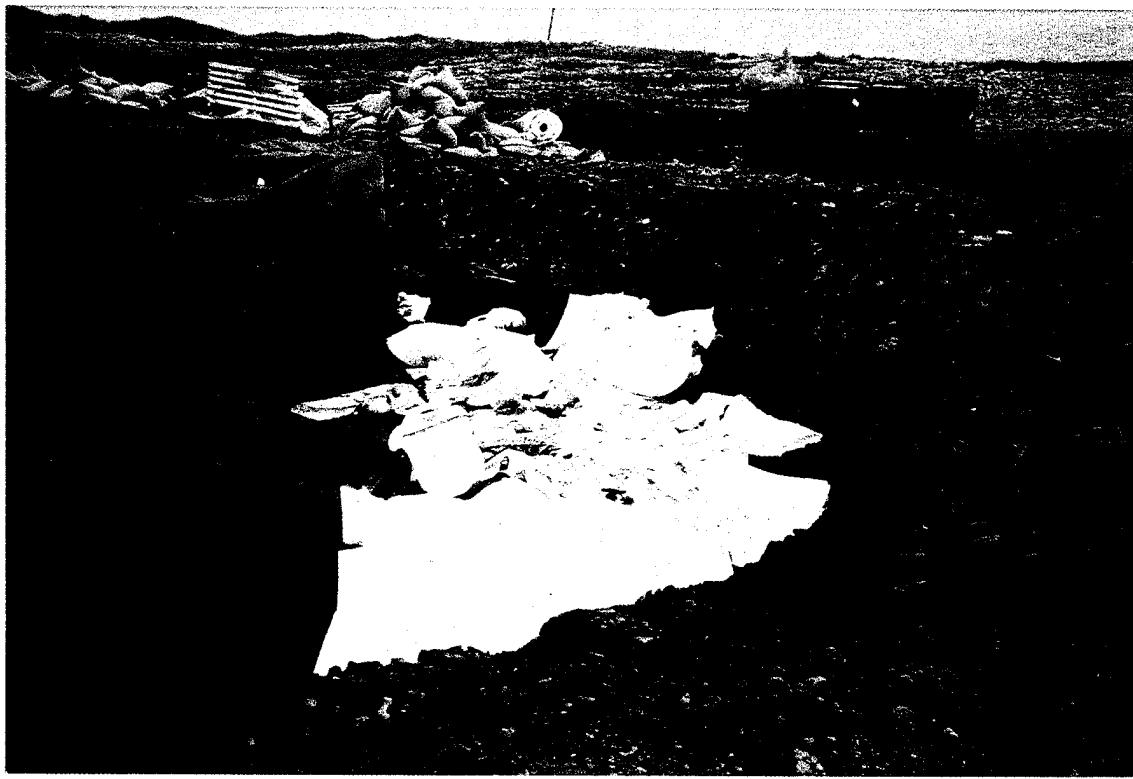

**Photograph 30:** During late June 1995, the backfilled excavation was fertilized and seeded.

**Photograph 31:** By mid-August 1995, the seed had germinated and the backfilled area had started to revegetate.

**Photograph 32:** Liquids being pumped from the sump area of the containment cell.

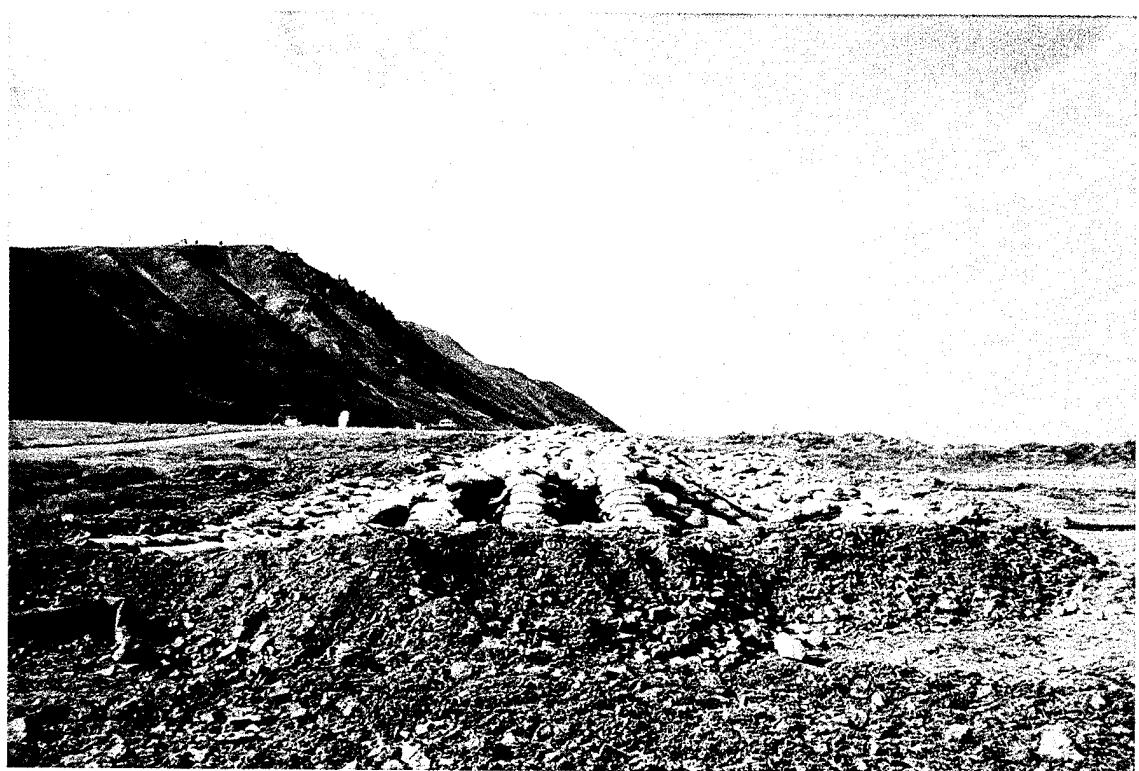

**Photograph 33:** Sorbent pads were used to collect residual oil on the rocks and soil in the sump.

**Photograph 34:** The liner was pulled back and the gravel berm pushed to the west.

**Photograph 35:** The liner was secured in place with gravel and sandbags.

**Photograph 36:** The new top liner was installed and secured with sandbags.

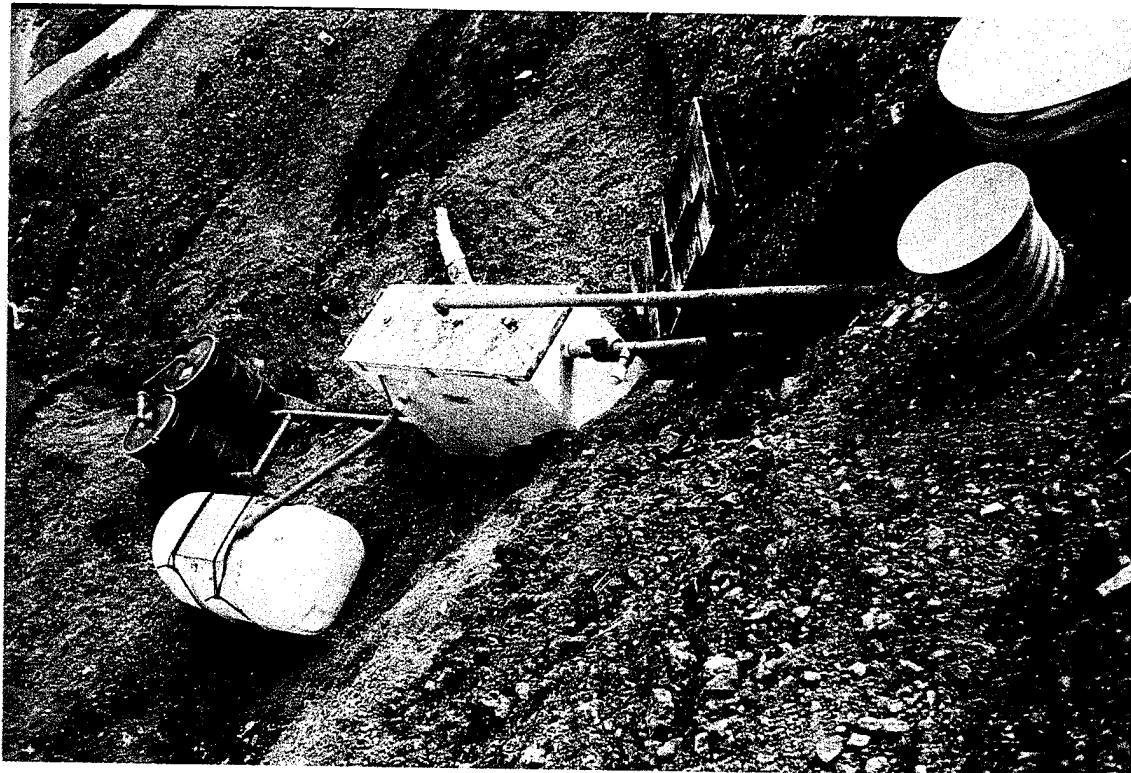

**Photograph 37:** The east and west trenches were sloped to the sump collection area.

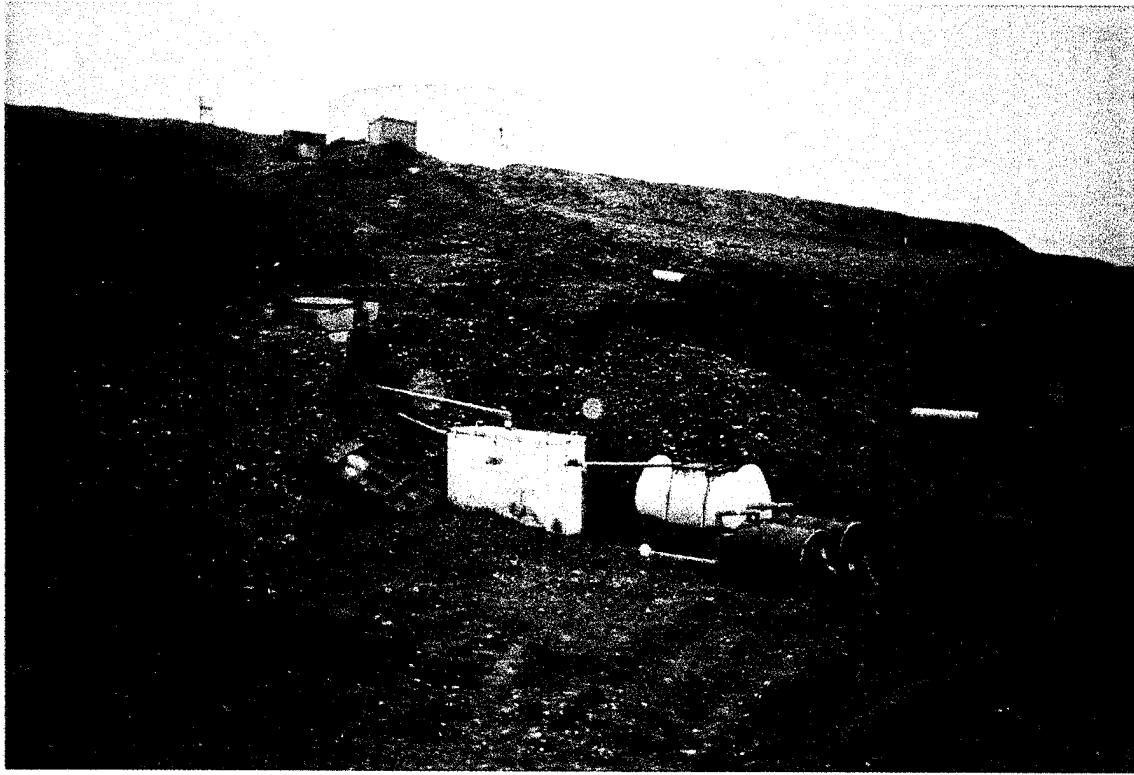

**Photograph 38:** The liner was placed on the bottom and downhill side of the trenches.

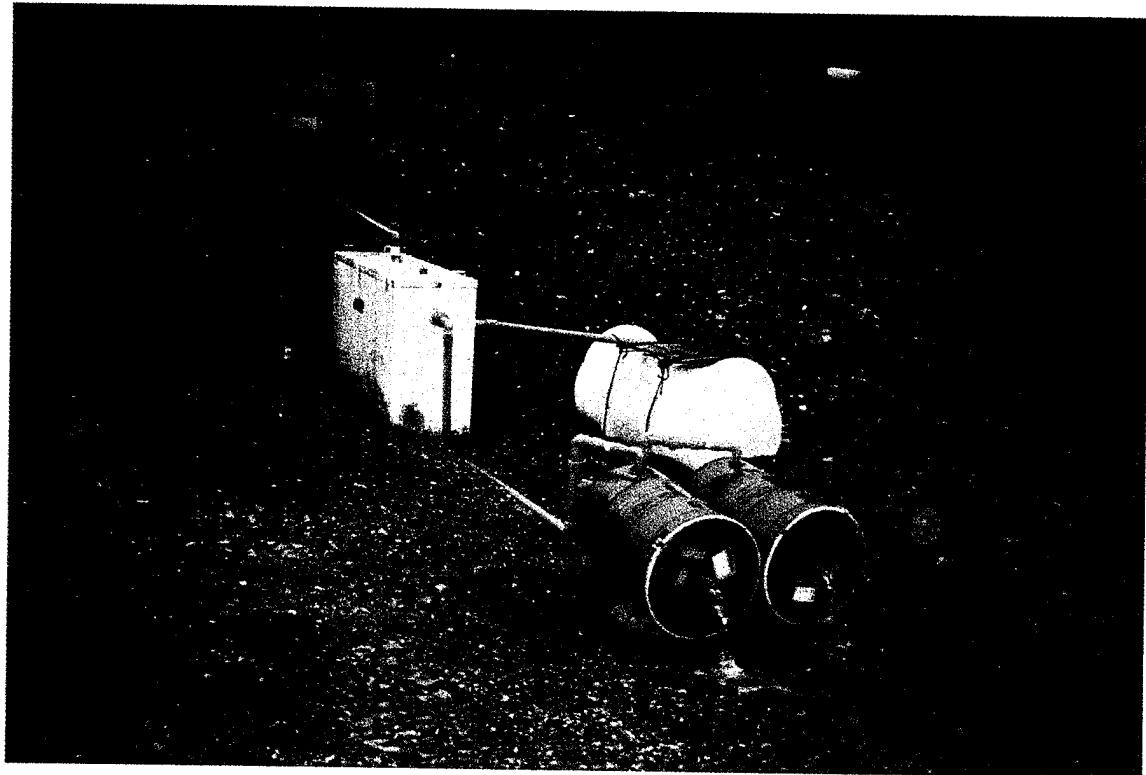

**Photograph 39:** The sump consisted of a culvert with a welded metal base.

**Photograph 40:** The sump was piped into the oil/water separator that skimmed and diverted diesel to the product collection tank. Water effluent from the oil/water separator was piped into two carbon adsorption units for treatment prior to discharge.

**Photograph 41:** During August 1995, the carbon units were re-piped in a horizontal position.

**Photograph 42:** The operating collection and treatment system.

Released By *Thomas Poston*

Sample Remarks: SAMPLE COLLECTED BY: C.C. AND JOHN P. FRERICHS. RRO - UNKNOWN HYDROCARBON WITH SEVERAL PEAKS. DRO - HEAVIER HYDROCARBONS CONTRIBUTING TO DIESEL RANGE QUANTITATION. SURROGATE RECOVERIES OUTSIDE OF ACCEPTABLE RANGE DUE TO MATRIX INTERFERENCE. J- INDICATES AN ANALYTE DETECTED BELOW THE CALIBRATION RANGE.

Released By *Stephen Preston*

Sample Remarks: COLLECTED BY:C.C. AND JOHN P. FRERICHS.HIGH CONCENTRATIONS. RRO-TYPICAL PATTERN FOR OIL BLEND & LIGHTER HYDROCARBONS. DRG-TYPICAL PATTERN FOR DIESEL. HEAVIER HYDROCARBONS CONTRIBUTING TO DIESEL RANGE QUANTITATION. SURR. RECOV. OUTSIDE OF ACCEPTABLE RANGE DUE TO MATRIX INTERFERENCE. J-INDICATES AN ANALYTE DETECTED BELOW THE CALIBRATION RANGE.

Ordered By JOHN FRERICHS  
Project Name CAPE LISBURN-LF01  
Project# 41096-614-02  
PWSID UA

WORK Order 14633  
Printed Date 05/31/95 2 15:00 hrs.  
Collected Date 05/08/95 2 09:10 hrs.  
Received Date 05/11/95 2 12:30 hrs.  
Technical Director STEPHEN C. EDE

Released By *Thomas Poston*

Sample Remarks: SAMPLE COLLECTED BY: C.C. AND JOHN P. FRERICHS. HIGH CONCENTRATIONS.

RRO - TYPICAL PATTERN FOR OIL BLEND & LIGHTER HYDROCARBONS. DRO -  
TYPICAL PATTERN FOR DIESEL. HEAVIER HYDROCARBONS CONTRIBUTING TO  
DIESEL RANGE QUANTITATION. SURROGATE RECOVERIES OUTSIDE OF ACCEPTABLE  
RANGE DUE TO MATRIX INTERFERENCE.

Released By *Thomas Pastor*

Sample Remarks: COLLECTED BY: C.C. & JOHN P. FRERICHS. HIGH CONCENTRATIONS. RRO-TYPICAL PATTERN FOR OIL BLEND AND LIGHTER HYDROCARBONS. DRO-TYPICAL PATTERN FOR DIESEL. HEAVIER HYDROCARBONS CONTRIBUTING TO DIESEL RANGE QUANTITATION. SURR. RECCV. OUTSIDE OF ACCEPTABLE RANGE DUE TO MATRIX INTERFERENCE. J-INDICATES AN ANALYTE DETECTED BELOW THE CALIBRATION RANGE.

Client Sample ID LIS-LF01-5FP09

Client Name ICF KAISER ENGINEERING  
 Ordered By JOHN FRERICHS  
 Project Name CAPE LISBURNE (DEW LINE) IRA  
 Project# 41096-614-02  
 PWSID UA

WORK Order 15995  
 Printed Date 08/15/95 @ 14:25 hrs.  
 Collected Date 06/26/95 @ 14:30 hrs.  
 Received Date 06/30/95 @ 10:00 hrs.

Technical Director STEPHEN C. EDE

Released By *Sharon Poston*

Sample Remarks: QUOTE #1962.8240-TRICHLOROETHYLENE REPORTED OVER CALIBRATION RANGE  
 RERUN 7/11/95 PAST HOLDING TIME FOR CONFIRMATION RUN FOUND 8.92 MG/L  
 TRICHLOROETHYLENE. SAMPLE WAS SPIKED WITH 1242 AT 0.5 MG/ML IN SOIL DUE  
 TO MATRIX INTERFERENCE. E-IDENTIFIES COMPOUNDS WHOSE CONCEN. EXCEED THE  
 CALIB. RANGE OF THE INSTRUMENT FOR THAT SPEC. ANALYSIS. CORR. RESULTS.
